The annual report of Dr. A. S. M. Macgregor, medical officer of health for Glasgow, for the year 1930, discusses the question of the reorganization of hospital facilities in reference to the Local Government (Scotland) Act, 1929. The report points out that the operation of the Local Government Act has revealed unexpected problems, which would require careful inquiry and consideration, and that among these the foremost was the question of hospital provision. It is stated that in Glasgow there are some 6,200 hospital beds for all types of infectious and non-infectious diseases, and that the question of interchangeability between the different institutions has become a matter of great importance. It had become evident that a good deal of hospital provision—about 25 per cent.—was devoted to the care of the aged infirm and those who were chronically ill with various permanent ailments, while, at the same time, the demand in winter for the treatment of acute cases was leading to overcrowding of hospital wards. Many of the aged and infirm could be accommodated in institutions other than up-to-date hospitals; with chronic infirmities classification was more difficult. An abrupt separation as between acute and chronic ailments was to be avoided. The adequacy of hospital accommodation was also closely bound up with the possibilities of home treatment for the sick poor; too free use of hospital accommodation, for minor ailments and for affections which could be nursed at home, tended to restrict the usefulness of hospitals. It was evident that an improved outdoor medical service, associated with a domiciliary nursing scheme, would materially conserve hospital accommodation, and would in time become an essential auxiliary to hospital treatment. Co-operation between council hospitals and voluntary hospitals was already close in many respects, and would undoubtedly become closer. The function of the out-patient clinic as a diagnostic centre in association with hospital work was also an outstanding matter for consideration. According to the report, the general death rate in Glasgow during the year was 14.2 per 1,000 as compared with 16.3 for the preceding year. It is satisfactory to note that the number of cases of pulmonary tuberculosis notified during the year was only 1,687, or about two-thirds of that notified as recently as ten to fifteen years ago. With regard to new housing accommodation, the report states that half of the new houses provided were three-apartment dwellings, and that this type of house is the most popular and the most serviceable for the relief of overcrowding.

Royal Infirmary of Edinburgh

An account of the work of the Royal Infirmary of Edinburgh was given by Mr. Russell Paton, organizing secretary of the League of Subscribers, at a meeting in Edinburgh on November 19th. Referring to the present need for extension of the institution, he said that every citizen must ask how far it would be possible to maintain the voluntary principle intact, or whether there would be a commingling of voluntary, municipal, and State-aided hospitals in the system of the future. The lecturer gave a brief sketch of the origin and history of the Royal Infirmary, and indicated the development that had taken place in recent years; in the past year, he said, some 5,000 cases had been treated on the medical side as compared with 4,300 twenty years ago, while the number of surgical cases had been 14,600 as compared with half that number at the beginning of the same period. Another important factor was that twenty years ago the cases in the Infirmary were fairly evenly divided between the town and the country, whereas in the past year 8,700 cases had come from the city, and 10,400 from the country districts of Scotland. The waiting list was another pressing consideration; in the present month it included some 2,000 cases, the majority of which were surgical. Important extensions were in contemplation at the present time, and when these were completed an additional £90,000 per annum would be required to carry on the institution. The speaker was convinced that the voluntary system was not exhausted, and that both in management and in finance it produced an atmosphere peculiarly helpful to hospital service.

Child Welfare in Edinburgh

A toddlers' playground was opened by Lady Findlay, D.B.E., at Portobello, Edinburgh, on November 14th. Councillor Mrs. Somerville, who presided, said there were now fifteen of these open-air playgrounds in Edinburgh, each taking care of some thirty or forty young children. There were also nine nursery schools in Edinburgh, which took in children for the whole day, and provided them with something in the nature of education. Lady Findlay, in declaring the playground open, said that those who had considered the problem of child welfare in a crowded city must realize the importance of centres such as this, where small children between 2 and 5 years old could be safely kept in ideal conditions of health for some hours while the mother was busy. There was also an advantage to the children themselves in the inculcation at an early age of elementary habits of order by taking part in organized games; this sowed the seeds of good citizenship. Dr. Findlay of the corporation child welfare department spoke with appreciation of the work which was done by voluntary helpers to make these centres a success. It was announced that the new playground and the hut attached to it were opened free of debt. The sum of £25 had been received from the corporation, £50 from the Voluntary Health Workers' Association, £40 from the Day Nursery Association, and the rest of the money had been collected by voluntary workers, while the children themselves had contributed £4 in halfpennies and pennies. The hut, with its equipment, had cost about £280, and between £70 and £80 a year would be required to carry on the work.

Buckie Typhoid Epidemic

An epidemic of typhoid fever has prevailed in Buckie, Banffshire, for the past ten weeks. Thirty-four cases in all were notified, but the epidemic is now regarded as over because no fresh cases have been notified since October 5th. Most of the cases have been treated in the Campbell Hospital; 21 have been discharged during the past six weeks, leaving 13 cases still under treatment. There have been no deaths. The outbreak was traced to a "carrier" who was temporarily resident near one of the sources of the town's water supply. This source was, in consequence, cut off, and, since the discovery of the "carrier," water from it has not been allowed to enter the supply of the town.

Central Midwives Board

The examinations of the Central Midwives Board for Scotland, held simultaneously in Edinburgh, Glasgow, Dundee, and Aberdeen, have just concluded with the following results. Out of 155 candidates 142 passed. Of the successful candidates, 62 were trained at the Royal Maternity Hospital, Glasgow, 27 at the Royal Maternity Hospital, Edinburgh, 18 at the Elsie Inglis Memorial Hospital, Edinburgh, 1 at the Maternity Hospital, Aberdeen, 12 at the Royal Infirmary, Dundee, 3 at Stobhill Hospital, 7 at Govan Maternity Hospital, 5 at Bellshill Hospital, 4 at the Royal Infirmary, Perth, and 3 at Barshaw Hospital, Paisley.

Ireland

Medical Certification under National Health Insurance

In a letter issued by the assistant secretary (Mr. J. A. Duffy) of the National Health Insurance Committee to medical certifiers under the National Health Commission, attention is directed to the fact that the number of medical certificates issued in the Irish Free State under the medical certification scheme has increased by 77 per cent.—from 709,262 in 1923 to 1,253,224 in 1930—and that during the same period the amount expended by approved societies on sickness and disablement benefits has risen from £354,828 to £617,699, an increase of 74 per cent. Having considered the report of the subcommittee, consisting of representatives of the medical profession and of approved societies, appointed to investigate the causes of this increase in certification, the Commission desires to impress on medical certifiers the following points: (*a*) A medical certificate of incapacity issued to a person who is not incapable of work places a burden on the national health insurance fund for which no financial provision has been made. This practice, if continued, must lead to financial instability. (*b*) Before receiving a medical certificate of incapacity every applicant should be conscientiously examined, if necessary at his own home. (*c*) If the certifier is satisfied that the applicant is incapable of work, owing to some specific disease, or to bodily or mental disablement, he should issue a certificate. (*d*) A certificate of incapacity should be based solely on the certifier's honest opinion as to the state of the applicant's health as disclosed by examination. No certificate should be issued on sympathetic grounds—for example, unemployment or poverty. (*e*) If the certifier is satisfied that the applicant is not incapable of work he should without hesitation refuse to issue a certificate and notify the Commission on the appropriate form. (*f*) If the certifier is in doubt he should apply immediately for a second opinion under the District Medical Referee Scheme. (*g*) When an applicant to whom a certificate has been issued is found fit for work at once or within not more than three days, he should receive a final certificate to that effect without delay. (*h*) A certifier must not issue a certificate to any other than the insured person to whom it applies. The letter also states that in accordance with the recommendations made by the subcommittee it has been decided that the maximum monetary penalty to which certifiers are liable for breaches of the agreement shall be raised from £5 to £20 as from the date of the letter referred to, and that cases of serious irregularity shall be reported to the Medical Registration Council. The Commissioners express the hope that they will have the co-operation of every medical certifier in dealing with the serious position which has arisen, and that an immediate improvement in certification will ensue.

Belfast Maternity Hospital

At the half-yearly meeting of the Maternity Hospital it was announced that the joint building fund of the Maternity and Royal Victoria Hospitals in Belfast amounted to £88,204. The report showed that the number of women admitted to the wards was 671, as compared with 774 during the same period last year. Of these, 449 were admitted for confinement, 222 for treatment, and 454 babies were born, including ten sets of twins. In the district there were also fewer patients—158 as compared with 201—and 161 babies were born. At the baby clinic 195 births were recorded, and 1,018 second visits. The ante-natal department was stated to be of the greatest benefit to mothers and infants. There had been 892 new patients and 2,303 re-attendances. Of the nine nurses who entered for the Central Midwives Board examination, eight had passed. In regard to the financial statement receipts amounted to £2,528, and expenditure to £2,612, leaving an adverse balance of £84, but as collectors were only beginning to make their returns the committee was not apprehensive of any appreciable debit at the end of the financial year. The annual grant of £1,000 from the Belfast Corporation enabled the committee to carry on the very important ante-natal department. It is confidently expected that in the course of the coming year the Royal Victoria Hospital will be in a position to take over this hospital, with its assests and responsibilities.

Belfast Children's Hospital

In order to stimulate interest in the work of this hospital, the splendid new building outside the city's industrial belt on the Falls Road was utilized recently for the annual "Pound Day" in connexion with this institution. Many visitors took advantage of the opportunity to show in a practical manner their interest in one of the greatest philanthropic works in the city. Three years have already been spent in preparing the new home for the Children's Hospital, and though it is difficult at present to say definitely when the activities of the hospital will be transferred from Queen Street, the constructional work is expected to be finished next year.

England and Wales

Vital Statistics for 1930

The Registrar-General's Statistical Review of England and Wales for 1930, Tables, Part II, Civil, may be obtained from H.M. Stationery Office (2s.). As previously the volume contains statistics of population, births, marriages, and divorces, registers of electors, and vital statistics of the British Dominions. A table is given showing the populations of England and Wales, Scotland, and Ireland as enumerated at each Census from 1821 to 1921, and so estimated for each year 1891 to 1930 inclusive. The number of marriages solemnized in England and Wales during the year 1930 was 315,109, against 313,316 in the previous year. The rate in both years was 15.8 persons married per 1,000 persons living. This rate is the highest recorded since 1921, notwithstanding the present economic depression. Of the total marriages 31 per cent. were solemnized during the third quarter, or more than double the number during the March quarter. This preference for the third quarter has been constant since the beginning of the present century, prior to which the fourth quarter had been the favourite quarter for marriage. It is interesting to observe that 22 males and 699 females married at 16 years of age, the lowest legal age at which marriages may be solemnized, and that while the 22 males married females up to 23 years of age, the 699 females married males of varying ages between 16 and 49 years of age; in only five cases were the bride and bridegroom of the same age. The number of decrees nisi made absolute in respect of dissolution or annulment of marriage was 3,563, an increase of 167 over the figure for the preceding year. The births registered during the year totalled 648,811, an increase of 5,138, though the rate of 16.3 per 1,000 of the population remained the same. This increase in the number of births is probably in consequence of the high marriage rates recorded during the last two years. The proportion of the sexes in the births registered during the year was 1,044 males to 1,000 females, thus continuing the approximate proportion of recent years. It is interesting to note that there was at the end of the year 1930 a total of 157,948,940 names in

the Registrar General's index available to the general public for searches in the registers of births, marriages and deaths. The statistics relating to parliamentary electors give the figures for the 1930 register for England and Wales as 12,101,108 males and 13,629,399 females, making a total of 25,730,507 electors, with increases of 234,314 and 400,400 in the respective sexes over the preceding year.

New Liverpool Radium Institute

The foundation stone of the new Liverpool Radium Institute and Hospital for Cancer and Skin Diseases, in Myrtle Street, was laid on November 23rd by the president, Lord Derby. The chairman of the hospital, Alderman H. M. Miller, said that the time had come when reconstruction, rearrangement, and enlargement had been found to be absolutely necessary. The committee had long contemplated such a step—some might say they had been too long—but nothing had been decided without careful consideration. They had been determined that everything should be of the highest quality, and the plans had been revised several times. Replying to the vote of thanks, Lord Derby said that the value of a hospital lay as much in its research work as in its treatment, and that these two departments together could only be carried on successfully provided there was the fullest confidence and co-operation between them. Cancer was the most dreaded disease. For every person who had it there were 400 to 500 people who imagined at one time or another that they had the disease, or were going to get it. Fear of the disease was about as bad as having it. This hospital dealt with cancer, and was prepared to use not only radium, but every kind of treatment, in cancer cases that the medical profession recommended. The hospital received patients from the whole of West Lancashire, West Cheshire, South Westmorland, North Wales, and the Isle of Man. Even in these troublous times, when rigorous economy was necessary, it was essential that all who had the means should help to alleviate sufferings which that hospital undoubtedly could ameliorate. The new hospital will cost £70,000 and will be on the most up-to-date lines. A deep x ray therapy equipment is already installed.

University of London and National Economy

At the meeting of the London County Council on November 17th, a letter was read from Lord Macmillan, chairman of the Court of London University, stating that the Court had been much concerned with the financial position of the University, in view of the imperative need at the present time for national economy. The University Grants Committee had stated that it would have no longer at its disposal during the current quinquennium any funds for capital grants, but that the annual recurrent grants from the Treasury would be maintained at their present figure, subject to the overriding necessities of national finance. The Grants Committee had added that it was the hope of the Government that the universities and colleges, while maintaining a high standard of economical administration, would find it possible to avoid any serious curtailment of their work as centres of advanced education and research, and would continue to receive in the fullest measure that circumstances allowed, the assistance of all bodies and persons from whom they had learned to look for sympathy and support. Lord Macmillan proceeded to say that the Court had had before it figures showing the effect on the finances of the L.C.C. of the present national emergency, and had been impressed with the seriousness of the situation. Recognizing the generous treatment it had received at the hands of the Council, it now offered to forgo, for the Council's current financial year and for the whole of the financial year 1932-33, 10 per cent. of the annual maintenance grant of £125,000 which the Council had voted to the Court. Any claims on the capital grant promised by the Council (£250,000) for the development of the Bloomsbury site would also be postponed until after March, 1933. Lord Macmillan added: "It is inevitable that this diminution of its resources will necessitate the curtailment and postponement of developments in the activities of the University which in normal times the Court would have regarded itself as in duty bound to foster and encourage. It does not doubt that the Council will bear this fact in mind when the present period of financial strain is over." The Council accorded its thanks to the University Court for its generous action.

King's College Hospital: Service of Remembrance

The annual service of remembrance and thanksgiving for the lives of those commemorated in connexion with the work of the institution was held in the chapel of King's College Hospital, Denmark Hill, on November 19th, and was largely attended by the members of the medical, nursing, and administrative staff, and by other friends of the hospital. The service this year included the dedication of a memorial to the late Dr. David James Graham of Edinburgh, and the address was given by Dr. Graham's brother, the Right Rev. J. A. Graham, D.D., Moderator of the Church of Scotland. This memorial, which is believed to be unique among hospital memorials, is covered by the following by-law: "Every person endowing the hospital with an investment (approved by the committee of management) producing at the time an annual income of not less than £5 5s. may have the name of any person placed and retained as an endowment or memorial governor on the list of governors of the hospital." After evening prayer, the lessons being read by Lord Gorell, chairman of the governing body, alms were received, including the gift intended to create the late Dr. Graham a memorial governor. The Moderator in his address, spoke of the Christ-likeness of the ministry of healing, pointed out the fine symbolism whereby the chapel at King's College Hospital is at the very centre of the great institution, and expressed the hope that the voluntary spirit which evoked such love and service on behalf of the sick would never be suffered to disappear. He also made allusion to the circumstance whereby his late brother, although not connected with King's College—for the whole of his educational and professional career, except for his war service in France, was spent north of the Tweed—should, by virtue of an anonymous gift, be created a perpetual governor of this great London hospital. He spoke of David Graham as an outstanding example of a beloved physician, and said that although it was nearly three years since he passed away, and a much longer time since he gave up active practice in a vain pursuit of health, he (the speaker) was constantly coming upon persons in Edinburgh who spoke of him with gratitude and affection. A brief memorial notice of Dr. Graham appeared in our issue of January 26th, 1929 (p. 181).

Royal Dental Hospital of London

The twenty-second annual clinical at-home took place at the Royal Dental Hospital School of Dental Surgery, Leicester Square, on November 21st. The morning programme included a number of demonstrations both at the hospital and in the operating theatre at Charing Cross, and in the afternoon there was an exhibition of clinical cases. In the large conservation room at the top of the building some thirty general cases and forty orthodontic cases, particularly of children, were exhibited as well as photographs, models, and specimens of pathological interest from the museum. The appliance room, with prosthetic cases, the mechanical laboratory with students' work, the x ray department with an exhibition of skiagrams, and the John Hunter Hall

research department, with an exhibition of photomicrographs and drawings by members of the Research Committee, were also open for inspection. In the evening past and present students, with the staff, numbering altogether 180, gathered at dinner under the chairmanship of Sir Norman Bennett. Among the guests were the president of the British Dental Association (Mr. W. Kittow), the deans of three other schools (Guy's, Royal Free, and London Hospital), and a number of examiners. Sir Norman Bennett described himself as the junior member of the teaching staff, having recently been appointed lecturer on orthodontics and director of the orthodontic department. He remarked that the present hospital owed its existence, not to the benevolent public, but almost entirely to the benevolent profession, because it was the subscriptions of students of the old hospital, also in Leicester Square, which made the new hospital, built thirty years ago, possible. In those earlier days there was very little competition among dental hospitals, but since then schools of dental surgery had been developed at a number of general hospitals, and the Royal Dental had been at some disadvantage because, until lately, it had had no beds. This had been remedied by a provision at Charing Cross Hospital, and now the students had an opportunity of learning the surgical side of dentistry better than they could learn it, he believed, at any other hospital in the kingdom. With regard to orthodontic treatment, Sir Norman Bennett said that there was a growing demand for such treatment, which must be met, not by a number of orthodontic specialists, but by general dental practitioners. The orthodontic treatment required in practice could be taught in hospital on simple lines, and provision was being made for short post-graduate courses in the subject. Mr. H. Stobie, the dean of the school, described the changes which had taken place on the staff during the year, and mentioned that the teaching of chemistry and physics at the hospital as pre-dental subjects had been abandoned, because it was forcibly borne in upon the management of the school that the teaching of these subjects was being done outside, at public schools and other institutions, and the entry of students for these particular purposes did not justify the upkeep of the department. He also reported that the curriculum for the degree of London University (B.D.S.) had been amended so that it would be possible for a student who had been studying for that degree, should any accident befall him and prevent the completion of his studies, to go on for the L.D.S. The school had slightly improved on its numbers this year, but it felt the competition, not only of its friendly rivals in the metropolis, but of provincial schools, which were now so excellent that students did not come up to London as formerly. Mr. N. J. Ainsworth proposed the toast of "The Guests," to which a response was made by Professor T. B. Johnston, dean of Guy's Hospital Medical School, who referred to the friendly helpfulness existing between the two schools; and the proceedings came to an end with the toast of "The Chairman," proposed by Mr. W. H. Dolamore.

Ambulance Service

The Home [illegible] Ambulance Committee pays a warm tribute in its report for the quarter ending September 30th, to the zeal and efficiency of the members of its roadside organization. We have frequently commented on the public spirit of these voluntary workers who devote their leisure time to the care of victims of traffic accidents, and to the establishment of first-aid stations at dangerous points on the highway. During the past few months a considerable increase has been made in the number of first-aid huts and boxes, several of the huts being so constructed that they can readily be moved from one site to the another. In this department of its activities, as well as in its ambulance work, the committee acknowledges the generous help of the Royal Automobile Club and the Automobile Association, and reminds its members that their efforts should be directed to the care of the sick and injured and not to the regulation of traffic and other matters which are properly dealt with by the police and by motoring organizations. The committee also refers to the high standard of work carried out by its mobile *x*-ray unit, and attributes the growing popularity of this service to the new equipment (described in a previous notice) and to the co-operation of members of the medical profession. During the quarter, 28,354 patients were carried by the committee's ambulances, bringing the total number carried (at September 30th) up to over a million. At that date the ambulances numbered 319, including 120 affiliated stations. The customary table of work done in various counties is given at the end of the report.

Correspondence

RHEUMATOID ARTHRITIS

SIR,—May I ask your courtesy for one more short letter upon this subject. I have read with great interest the remarkable correspondence. Among other things, I have learned that such cases should *not* be treated with vaccines and also that every early and uncomplicated case can be *cured* by vaccines. I have also learnt that the advanced morbid changes that may occur in the joints can be produced by vasomotor disturbances apart from any microbial infection. I have been told that if I do not treat a case with vaccines other methods are too drastic, and I have wandered into romantic scenes of warfare and profiteering by streptococci. This correspondence, so far as I am concerned, has served its purpose and confirms me in my creed, which is this: that to be dogmatic in the present state of our knowledge of rheumatoid arthritis is an insult to my own intelligence, is an insult to the intelligence of others who are thinking and working along different lines, and an insult to the science of medicine.—I am, etc.,

London, W.1, Nov. 20th. F. JOHN POYNTON.

PHYSICAL MEDICINE AND MEDICAL HYDROLOGY

SIR,—The formation of a group within the British Medical Association of practitioners interested in physical medicine is a reminder that there is at present no definition of this vast subject. I suppose it means the study of the medical uses of the physical energies, or the many forms of the one energy by which we live. If that is so, a distinction might reasonably be drawn between physical remedies as they are in nature and those which require apparatus to produce them. The first are ever present, elemental, profound, essential for life; the second, like artificial heat and light, are undoubtedly essential in civilized life, and most valuable in the work of healing. Their elaboration in recent years has been phenomenal, and is daily becoming more complicated and costly. Witness the varied apparatus and technique of artificial radiation alone, and the place it is taking even in the installations of natural health resorts.

A few months ago the Royal Society of Medicine put an end to its Section of Balneology and Climatology, of which I had been a member for thirty-six years, and founded a new Section of Physical Medicine. I was a little reassured when at the same time the British Medical Association created a Section of Hydrology and Climatology at its Annual Meeting at Eastbourne. Surely it

would be a pity to obliterate the only medical organization which directly represents so great a field of medical practice as the waters, coasts, and climates of the British Empire.

Physical medicine is a great name, but we must recollect that up till the present time, in the societies and congresses and literature of Europe and the United States, physiotherapy, or physical treatment, has signified almost entirely the use of energies artificially produced. Their development has been most important, ingenious, and spectacular. But they cannot cover more than half the field. To take, for example, the use of physical remedies in medical hydrology. In opening the Section at Eastbourne I reminded the members that the science and practice of hydrology was threefold: first, in relation to medicinal or mineral springs (crenotherapy); secondly, in relation to simple water (hydrotherapy), in which a new development was taking place in England by the provision of bath clinics in the towns; thirdly, in relation to the sea, the great mineral water in which life originated (thalassotherapy). The number and variety of marine health resorts in the British Islands was unsurpassed in any country, and, since all hydrological methods of treatment were affected by atmospheric conditions, it was necessary for hydrologists to be acquainted with the good and bad effects of climate in the evolution of disease.

A great work has yet to be done by students of hydrology in Great Britain. The uses of waters and of the various forms of baths require precise and experimental study. The same applies to the effect of sea bathing and marine climates on the vast numbers of delicate children referred to the coast, and to the prevention and arrest of disease in later life at the winter marine resorts. How is this work to be carried out? Surely not by depriving British hydrology of medical representation. A science can only flourish in a country where it has a local habitation and a name. Let us in England beware lest, in trying to erect a whole, we destroy an essential part.—I am, etc.,

London, W.1, Nov. 21st. R. FORTESCUE FOX.

VITAMINS AND BONE GROWTH

SIR,—In the annotation in your issue of November 21st on vitamins and bone growth a statement was made which caused a clinician of some age like myself to rub my eyes and wonder at the ease and assurance of comparative youth. The statement is: "Most writers at that period [the early years of this century] emphasized the disadvantages of cod-liver oil" in the treatment of rickets. I turned to my bookshelves, which contain more pre-war than post-war textbooks, and pulling down one after the other I failed to find any support for your assertion. The first three books which I consulted, 1909, 1911, and 1913, said respectively: "Treatment resolves itself into" alterations in the diet "and the administration of cod-liver oil"; "cod-liver oil takes the first place"; and "ol. morrhuae is the only drug of any real value." In fact, Sir, my recollection of that remote period was accurate, and not only did every respectable authority on the diseases of children recommend the use of the oil, but in oral teaching its great benefits were emphatically stressed by every teacher with whom I came in contact. In short, the statement is thoroughly misleading.

But you go on to stress the great advance which the experimental work on rickets has made in the treatment of that disease. I do not wish to decry the value of experimental work, least of all the brilliant researches on deficiency diseases, but the clinical facts are against your assumption. Rickets, as we workers knew it in the 1890-1900 period, began to disappear in the 1900-10 period, and after 1910 severe rickets was becoming as rare a disease as it is to-day. The change was due, in my opinion—and this, of course, is merely an opinion—to the alteration in the methods of feeding the babies, and, above all, to the beneficent influence of the infant welfare movement. Before 1900 the long-tube feeder was almost universal, and breast-feeding was almost a lost art. Between 1900 and 1910 breast-feeding again became recognized as the best method of feeding, and the long-tube feeder was relegated to the shelves from which it never should have come. To these two causes, together with the abundant use of cod-liver oil, is due the great fall in the incidence of severe rickets, a fall which occurred for the most part before the experimental work on vitamins had been published.

I would add that it is a mistake to suppose that the disease has disappeared: at intervals, which I hope are becoming less frequent, we still see rickety deformities just as bad as in the dark days of the benighted Victorian period.—I am, etc.,

London, W., Nov. 22nd. HUGH THURSFIELD.

MICROCYTIC ANAEMIA

SIR,—May I raise a respectful protest against the adoption of the term "microcytic anaemia" as used by Dr. L. J. Witts in your issue of November 14th.

He adopts the term to describe a definite group of cases of chronic idiopathic anaemia (normoblastic, mostly achlorhydric and in women of middle age) "in which the mean diameter of the red cells is usually diminished and never raised." He, however, gives no measurements in this very valuable paper. Judging from my own experience, I strongly suspect that the size of the red cells will be within limits of normal, whereas the term "microcytic" surely implies cells smaller than normal. My only claim to speak is that I have measured with the halo-meter (*British Medical Journal*, July 13th, 1929) the red cells of hundreds of patients with and without anaemia. This little instrument—which I find clinically reliable, provided the film is thin and the largest diffraction halo is selected for measurement—picks out pernicious anaemia by its macrocytes (averaging about 8 microns), and distinguishes acholuric jaundice anaemia by its microcytes (about 6.4 microns). Normal people, and other anaemias, have red cells whose average size ranges from 7.6 to 7.9 microns (I cannot detail the few exceptions here). In this way bloods can be arranged by their average cell diameters into three groups—macrocytic, microcytic, and "normocytic." It will be highly confusing to find, on measuring the red cells in an anaemia defined as microcytic, that their size is within limits of normal, even though small in comparison with pernicious anaemia. If this be the case, would "non-macrocytic" convey the intended meaning, and would "non-macrocytic idiopathic anaemia" embrace Dr. Witts's cases?

The essential feature to be emphasized in a name for this group of anaemias appears to be that, although they are idiopathic and resemble pernicious anaemia in many ways, yet their red cells are *not enlarged*—that is, non-macrocytic. This distinguishing feature would be revealed by the halo-meter in a few seconds.

I know of only one anaemia which merits the name "microcytic," and that is acholuric jaundice. The name "microcytic anaemia" for Dr. Witts's cases originated, I believe, only recently in North America. There may yet be time to find a less confusing name. It would be interesting to hear Dr. Witts's views (and measurements).

As regards the suspicion that this may be a new type of anaemia, I remember that Sir Byrom Bramwell published a striking series of anaemias curable by Blaud's pills, but only if given in massive doses. This was about twenty-five years ago, but I cannot find the reference.—I am, etc.,

Hull, Nov. 16th. F. C. EVE, M.D., F.R.C.P.

HOG'S STOMACH IN PERNICIOUS ANAEMIA

SIR,—In a note on the treatment of a case of pernicious anaemia with beef predigested with normal gastric juice, Dr. Astley Clarke (*Journal*, November 14th) remarks that some cases of pernicious anaemia relapse when treated with liver and hog's stomach, and " are not then benefited to the same extent—possibly not at all— " the second time. " Why is it so? "

The answer is that, assuming the diagnosis to be correct, the treatment has been incorrect or inadequate in one of the following ways: (1) inadequate dosage; (2) the use of an inactive preparation of hog's stomach; (3) the inactivation by heat of an adequate dose of an active preparation. All these points I have repeatedly stressed in the English medical literature. In two and a half years' observation of upwards of 240 cases of true pernicious anaemia I have never found a relapse after the institution of active and adequate hog's stomach therapy. The average maintenance dose is usually half an ounce of desiccated hog's stomach per day; in some cases the full ounce is required, and this should be insisted upon where postero-lateral sclerosis is present. I have already drawn attention to the risk of employing inactive preparations of hog's stomach (*British Medical Journal*, 1931, ii, 76), and have referred to the use of normal gastric juice, which is active when not predigested with beef, provided it is given at meal times (*British Medical Journal*, 1930, i, 236). This has been confirmed, as Dr. Clarke has observed, in the American press. In all the research work so far published (both from Manchester and abroad) on this aspect of the problem, doses of eight ounces or more of gastric juice have been used, and the two ounces given by Dr. Clarke would not be sufficient to produce a prolonged remission, if at all, in pernicious anaemia. There are many difficulties besetting the unwary: (1) incubation for more than two to three hours; (2) too high or too prolonged an acidity destroys the activity; and (3) the supply of unsuitable gastric juice—even a normal secretion may vary very considerably. The fresh gastric mucosa of a pig may be substituted for normal human gastric juice.

It is a common observation that a blood transfusion, small doses of liver, stomach, and at times even iron and arsenic, will initiate remissions in pernicious anaemia; these will sometimes proceed until nearly normal blood pictures are obtained before relapse. It appears possible that the " remission " in Dr. Clarke's case was due to the blood transfusion rather than to the two ounces each of beef and normal gastric juice—no blood investigations are reported.

Beef predigested with normal gastric juice is much less palatable than an active hog's stomach preparation given in milk, with sardines or tomato, etc.—I am, etc.,

Royal Infirmary, Manchester, Nov. 18th. JOHN F. WILKINSON.

THE CARDIAC CYCLE

SIR,—In the first place, I would beg the hospitality of your columns to thank the reviewer for his courteous and sympathetic criticism of my venture along lines of investigation unfrequented and leading to conclusions here and there certainly " unorthodox " (that is, not sanctioned by current teaching); however, he credits me with " sincerity, enthusiasm, and lucidity," and I wish for no more generous words to express my desire, motives, and endeavour. In the next place, I wish to meet as far as I am able certain comments, which seem to indicate that I have not quite succeeded in making myself clear.

Thus, dealing with the genesis of the pulse-wave, as the result of an impact upon the closed aortic valve by the ventricular blood, during the isometric phase of the ventricular systole—in consequence of which a wave is " sent coursing through the aorta and its branchings down to the arterioles "—the case is admirably and succinctly stated But now, immediately upon the above, there comes a sentence which puzzled me much—namely, " The stretching of the arterial wall is regarded as the expression of ' momentum ' carried by the pulse-wave "—(I could recall no such isolated sentence). At this point, in direct sequence, came the definition of " momentum," as " the product of mass and rate of movement of the mass " (which had my full assent). This conceded, the sentence proceeds: " it is difficult to see how a vibration without any expulsion of blood into the arterial tree can add any momentum to that already possessed by the moving stream of blood before the impact strikes on the closed aortic valves." The comment ends here, and the puzzlement also, for at once it becomes clear that one form only of momentum is recognized within the circuit of the vessels—namely, that of the blood moving *en masse*. Is this so?

In my argument, from the beginning, I have laid stress on the fact that the circulation of the blood exhibits two forms of dynamism (the word should be justified since " dynamist " is recognized). The one, a movement of translation, which conveys the blood bodily to and from the heart; we shall all be agreed upon the fact and nature of this momentum. The other, a movement of vibration or undulation, which is confined to the branches of the arterial tree, and ceases in the arterioles. Clinically, it figures as the pulse-wave; what is its real nature? And has it momentum?

To answer these questions let us put the finger on the artery; it is lifted as the wave passes; substitute a lever, the lever is lifted in like manner; in either case the wave imparts *motion* to *mass*, and in so doing " does work " in the terms of the physicists. The lifted finger and lever are examples of momentum possessed and imparted by the pulse-wave. Can we put the Q.E.D. of the geometer here? No, because it has yet to be proved whether, if the impact of the isometric phase, as the rapidly rising tension of the intra-ventricular blood is brought to bear upon the aortic valve, is really the cause of the wave—whether, in this act some blood does or does not escape through the valve in spite of the adverse tension of the intra-aortic pressure, still in excess of that in the ventricle, for *ex hypothesi* we are still below the point o in the diagram.

At this stage we may ask: is it a canon in physics that an impact, which produces an undulation in a given liquid, must carry along with it a certain quantity of liquid, if the resultant wave is to possess momentum? *Fiat experimentum*. Let a stone be cast on to the surface of a river flowing smoothly; the immediate consequence is an undulation, starting from the point of impact and spreading in a series of widening circles to either bank. The actual form of the liquid movement constituting the wave is complicated, but it is *not* a movement of bodily translation, and it is wholly independent of the current of the river, to which it contributes nothing. Does this wave possess momentum? Let us see what happens as it meets with some floating object—for example, a child's sailing boat—and observe how the little craft is tossed about, up and down. Have we not here the manifestation of momentum? Yet the bare impact of the stone had no liquid accompaniment. All that happened as the stone sank was displacement, and perhaps in this movement we may find all that we need to account for the presence of momentum in the pulse-wave; for without doubt, as the tension-shock impinges upon the aortic valve there will be a bodily forward movement of the *unforced* valve, a displacement which carries with it a certain quantity of blood, this movement being permitted by the elasticity

the walls of the bulbus aortae. Upon this *action* will ow the kick of the elastic recoil as the *reaction*, equal l opposite, according to Newton's third law, and the ve will then speed on its way.—I am, etc.,

ondon, N W , Nov. 18th HARRINGTON SAINSBURY.

" FAILED FORCEPS " CASES

SIR,—The paper which I read on the obstetric forceps l its use was designed to remind my audience that uccessful attempts to deliver by forceps are still fre- ntly made, and to give an accurate account of the ults of misapplication of this instrument. For this pose I investigated the last 100 cases admitted to the erpool Maternity Hospital after forceps had been plied without success. These cases have been spread, im thankful to say, over no less than seven years. eir number, however, appears to be increasing. Twenty- o of them were admitted during the year 1930. I ght have mentioned the period involved, and would tainly have done so had it occurred to me that anyone uld think such a series of cases had been admitted hin a month or a year. The figure is of no statistical lue, because there are four other hospitals in this city h large obstetrical departments.

I therefore concentrated upon analysis of the causes of lure and its results. I can assure your correspondent ovember 21st, p 966) that my figures are of fact and t of fantasy It is perhaps as well that we are not all ted with his vivid imagination! If your correspondent d to deal with these cases, as I have to deal with many them, I think he would be less ready to accept them thout protest.—I am, etc.,

iverpool, No. 23rd M. A. DOBBIN CRAWFORD.

ETHER CONVULSIONS

SIR,—On Friday last, during my usual work at . Bartholomew's Hospital, I met my first case of ether nvulsions, and as it presents certain points that may be interest to other anaesthetists, I should like to record it

The patient was a boy, aged about 9, who had been dly smashed in a motor accident some time ago, and had d several operations for the grafting of skin to parts of the dy He had been under the care of Sir Harold Gillies, and ien I saw him it was to anaesthetize him for an appendicec- my for Mr Girling Ball. The position was this—his right rearm and right thigh were connected by a pedicle graft, d his lower abdomen was devoid of skin, which had been ed for the graft. Sir Harold divided the pedicle and Mr. ill then had to remove the appendix through an incision rallel to Poupart's ligament, and about half an inch above it. I gave the boy gas, oxygen, and ether endotracheally , the duction was normal, but after he had been under for about n minutes, I noticed a slight twitching about the outer side the left eye I at once shut off the ether and continued ith gas and oxygen, but the twitching continued and got vere, spreading to the face—in fact, it looked as though the cial nerve was being violently stimulated The twitching ntinued, and now it appeared as though his diaphragm was a state of spasm The left arm was twitching, but the right m and legs were not affected These spasms increased to i alarming extent I tried oxygen plus CO_2, but this did ot seem to have any effect. Next, as I thought that I must op the convulsions, I disconnected the endotracheal tube and ve him about 8 to 10 drops of chloroform on lint. He then came slightly cyanosed, so I discontinued the chloroform, id resumed with endotracheal oxygen alone; he now began breathe more regularly, and, after a few more minutes, breathe automatically. His pupils, which had been three- uarters dilated during his spasms, now became quite small, ot pin-point, but just a shade larger Throughout the whole ing, with the exception of the few seconds when he had ie chloroform, his colour was bright pink. As he was now breathing automatically and well, the appendicectomy was proceeded with, and for this he was given endotracheal gas and oxygen, which was occasionally passed over the surface of the ether On removal, the appendix was found to be dilated at its end and contained pus. At the conclusion of the operation his condition was fairly good, and he looked quite normal.

On considering the case, I think that in the early stage, just after induction, the patient may have had just a little too much ether, and this is the opinion that I have held with regard to some of the other cases that have been reported. I think that, in all probability, the reason why this boy recovered was that I started my efforts at remedy on the very first twitch, and did not wait for it to get pronounced. As it was, the twitches became very severe, and the patient's appearance was dreadful From the twitchings it appeared as though the facial and phrenic nerves were both violently stimulated

It will be noted that in this case the factor of sepsis is again present, as it has been in several other cases I have never met with one of these cases before amongst my own administrations, and sincerely hope that I may never meet with another —I am, etc ,

London, W 1, Nov 23rd H. EDMUND G BOYLE.

DEATHS ASSOCIATED WITH ANAESTHESIA

SIR,—Permit me to direct the attention of your readers to the following interesting statistics of deaths under or associated with anaesthesia in England and Wales, and in the United States For England and Wales I have derived the figures from the annual reports of the medical superintendent of the Registrar-General's office which give the data back to 1901. The results are as follows

Statistics of Deaths Under or Associated with Anaesthesia in England and Wales, 1901–29

Year	Total Deaths	Rate per 100,000
1901–1905	749	0 44
1906–1910	1 010	0 [illegible]
1911–1915	1 415	0 [illegible]
1916–1920	1,525	0 87
1921–1925	1 [illegible]0	1 04
1926	556	1 42
1927	[illegible]6	1 52
1928	656	1 68
1929	730	1 84

The rate of frequency of deaths under or associated with anaesthesia has therefore persistently increased from a minimum of 0 44 in 1901–5 to 1.84 during 1929, the highest rate thus far recorded. These rates may be compared with the corresponding rates for the United States Registration Area, 1922–29, as follows.

Statistics of Deaths Under or Associated with Anaesthesia in United States Registration Area, 1922–29

Year	Total Deaths.	Rate per 100,000
1922	513	0 55
1923	474	0 [illegible]
1924	558	0 [illegible]
1925	677	0 [illegible]
1926	654	0 [illegible]
1927	6[illegible]5	0 61
1928	5[illegible]9	0 48
1929	6[illegible]1	0 [illegible]
1922–1929	4 870	0 57

According to these comparative data the frequency rate of deaths under or associated with anaesthesia in England and Wales is three times the corresponding rate prevailing at the present time in the United States Unquestionably there is some reason for this enormous difference but no satisfactory explanation has been forthcoming —I am etc ,

FREDERICK L HOFFMAN.

Wellesley Hills, Mass , No. 11th

CARDIOSPASM

SIR,—Will you allow me space in which to comment on the criticisms of Dr. Geoffrey W. Rake (in the *Journal* of November 14th) upon my letter published on October 10th? Brevity is necessary in a letter, and renders impossible a full exposition of the subject, such as is contained in Chapter XVII of my book, *Chronic Intestinal Stasis*.

Dr. Rake denies my statement that in cardiospasm the stomach is always large, so that, in the erect posture, it drags upon the lower end of the oesophagus; if so, his experience differs from mine, and there is nothing to gain from discussion of a concrete matter of fact. But Dr. Rake's observations of the size of the stomach in his cases seem to have been a side issue of some histological examinations of the pylorus. I am curious to know how he came to be in a position to cut sections of the pylorus in all his cardiospasm cases; were they post-mortems, or does he operate in every case of cardiospasm, and remove a fragment of the pylorus for the microscope? This mystery must be cleared up. Dr. Rake's second point, again, is one of observed facts; he states that intestinal stasis is not a constant, even if it be a frequent, complication of cardiospasm. For my part, I adhere absolutely to my statement that chronic intestinal stasis is a pronounced feature of every case of cardiospasm, and I am certain that Dr. Rake's inability to confirm this will turn out to be because he has not taken the only certain means of proving or disproving it—namely, a complete *x*-ray investigation of the alimentary tract by a bismuth meal and a barium enema—as I have in all my cases of cardiospasm.

Dr. Rake asks me what tissues I mean by "those concerned"; obviously, those of the lower end of the oesophagus. But his last charge against me, that I invoke an idiosyncrasy to explain what I am unable to, is a just charge; my desire for brevity must again be my (admittedly inadequate) excuse. What I hoped to convey was that of many subjects of stasis with general toxaemia and a heavy stomach dragging upon the lower end of the (toxic) oesophagus, only a few become subjects of cardiospasm; if my explanation were a complete one, it would apply equally to all cases of the kind, and the degree of cardiospasm would be more or less proportional to the degree of toxaemia and to the force of the drag upon the oesophagus by the stomach. This, I am aware, is not so, and therefore I welcome the further investigations that Dr. Rake and others are carrying out.—I am, etc.,

London, W.1, Nov. 16th. ALFRED C. JORDAN.

THE GROWING AND MOVING BOY

SIR,—Those of us who are interested in the health of the growing child have noticed with satisfaction Lord Dawson's reference to the desirability of developing the positive side of school medical work as against the day-to-day work of remedying defects in which we are apt to become engrossed, and we cannot fail to be gratified that you have laid emphasis on this aspect of our work in your leading article published on November 14th. It is hardly correct, however, to say that it is "a new conception" or that it is "original." I cannot speak for the medical officers of public schools, but I would draw your attention to the fact that Dr. J. G. Woolham of Manchester has been publishing the results of his very valuable work on day-school children in the annual reports of the school medical officer of Manchester since 1923, and that Dr. J. V. A. Simpson has carried on similar investigations and reported upon them in the annual reports of the school medical officer of Torquay for the years 1925, 1927, and 1929. These reports will repay careful study, but it should be noted that physical efficiency tests of the type used in the Royal Air Force cannot be assumed to be generally or easily applicable to all sorts of school children. This aspect of the question is dealt with in a very brief note by Dr. Nancy K. Gibbs and Dr. C. W. Anderson in the annual report of the medical officer of health for Cardiff for 1930.—I am, etc.,

Cardiff, Nov. 17th. RALPH M. F. PICKEN.

CHILD GUIDANCE CLINICS

SIR,—In Sir George Newman's report on the health of the school child, epitomized in your issue of November 14th, stress is laid on three points of fundamental importance. It is pointed out that the medical inspection of the school child should be much more than a mere routine physical examination, and (1) that the question "Is this child developing according to the plan Nature has mapped out for him" should be kept in mind; (2) that the question should be answered only in the light of "an estimate of the whole individual"; and (3) that "it is of equal importance . . . to estimate the attitude of the mother. Is this parent to become an ally or not?" These three points are the basic principles of child guidance.

Child guidance clinics endeavour to develop the child to the utmost of his potentialities, with the help of the parent, utilizing in the process the knowledge obtained from an estimate of the whole individual, and of his environment. The report suggests that the investigation can be carried out by the school medical officer. This is not practicable, since the process is naturally a lengthy one, and, moreover, it is highly unlikely that the necessary experience of general and psychological medicine, educational psychology and teaching method, sociology, and economics would be possessed by any one individual. For this reason child guidance clinics employ a psychiatrist, an educational psychologist, and a social worker, each trained in the application of his or her specialty to children.

It has been found by experience that only in this way can satisfactory data be collected about each of the aspects of the child and his environment, and the employment of such a team method, though apparently so cumbersome, has been fully justified by the results obtained.—I am, etc.,

WILLIAM MOODIE, M.D., M.R.C.P.,
General Secretary, Child Guidance Council.
7, Buckingham Palace Gardens, S.W.1, Nov. 17th.

TEMPORARY TREATMENT WITHOUT CERTIFICATION

SIR,—It should surprise no one to find that Clause 5 of the Mental Treatment Act, 1930, has failed to function; but cannot this be attributed to the fact that there was no real need for its conception? This clause was an expression of the mighty efforts that are being made to find a way to avoid the "stigma of certification," and Dr. Robertson would insist on the need for psychiatrists and others to educate the public when a possible academic method of avoiding this "stigma" is evolved.

Would we not be better employed in educating the public away from this barbaric stigma which has attached itself to certification? If it is infamous to become of unsound mind, surely the infamy is perpetrated by the disease itself. Certification, resulting in detention in a mental hospital, can only help to conceal this infamy from friends, neighbours, business acquaintances, and the like. Usually against his will, if he retains the power of volition, the patient is removed to a sphere where his abnormality is humanely regarded in the same light as a cardiac or

pulmonary disorder. A legalized medical certificate is a necessary preliminary to placing a person of unsound mind under the control which is so essential for him and others, and frantic efforts to avoid it by subterfuge seem to show a lack of courage and a pandering to an archaic type of criticism.—I am, etc.,

London, N22, Nov. 22nd. E. JEFFREY SAMUEL.

SIR,—In connexion with this correspondence it may be of interest to recall that in 1835 a certain Dr. Unwin (sometime physician to Peckham House) wrote a pamphlet which concluded with the following summary:

1. Mental and nervous disorders are too much separated.
2. That a layman (magistrate) should have the decision in mental cases is a violation of every principle and every dictate of sense and reason.
3. The lunatic asylums, under some more sensible and less terrifying nomenclature, may be made of essential service to the community as in institutions for physical disease.

The first subject is still being discussed (without decision) by a committee in New York (see symposium in the *Journal of Nervous and Mental Disease*, 1931), the second received much attention, but was turned down by a recent Royal Commission; and the third has been only partially translated into practice by recent legislation—*ex uberibus sapientiæ*.—I am, etc.,

JAMES R. WHITWELL, M.B.

Royal Medico-Psychological Library, No. 23rd.

ASTHMA RESEARCH

SIR,—I believe that the claims made last week in your annotation on asthma, concerning Dr. Oriel's proteose cannot be justified. They are made, I feel sure, on the authority of the Asthma Research Council's "Report of progress from June 1st, 1930, to October 31st, 1931" I am on the Council's medical advisory committee, but the reports are not submitted to us.

The crux of the matter lies in the alleged *specific* dermal reaction of Dr. Oriel's proteose. With this his work is of the greatest possible importance to immunology, but without it the work loses all significance. During the past year I have done the following.

1. I first tried to make this proteose in my own laboratory. I had to guide me Dr. Oriel's original paper and his typewritten supplementary instructions. These seemed to be as much "proteose" from my own and from my assistants' urine as from that of asthmatic patients, so I got Dr. Oriel to come to give criticism and help. He said these previous directions were inadequate, and very kindly gave me additional advice. Even so, I still got the same heterodox results, and was unable to produce a substance from an asthmatic's urine which gave a specific dermal reaction on that patient.

2. I got Dr. Roche Lynch at St. Mary's Hospital to try to prepare proteose with the help of Dr. Oriel's supplementary instructions but nothing was produced which showed a specific reaction on the patients in question.

3. I sent urine from one of my out-patients at St. Mary's to Dr. Oriel's laboratory, he prepared and sent back the proteose but it gave no specific reaction.

4. Dr. Oriel said that possibly a patient's urine yielded the proteose at one time and not at another, so I arranged with him that I would take into our research wards at St. Mary's first one bad case of asthma and eczema, and then, a month later a second case of the same type, both cases were seen by Dr. Oriel and pronounced most suitable. I sent down daily specimens of urine to his laboratory covering periods of exacerbation and remission of the symptoms. Dr. Oriel sent me one specimen of proteose from the first case and two specimens (at about a week's interval) from the second. None of them gave a specific reaction. I offered to go on sending any amount of daily specimens from these cases but I understood Dr. Oriel to say that it was not worth trying any more.

5. This is most convincing of all to me. Dr. Oriel gave me proteose he had isolated from hay fever urine, this was said to give specific dermal reactions in 80 per cent. of all true hay fever cases. I found it quite non-specific on all cases tested.

6. I suggested several times that his proteose should be the topic of debate in the Asthma Research Club but Dr. Oriel haughtily cried off. In consequence of this I was brought that the specific action claim had been given up.

It is clear from the above that Dr. Oriel has given every help in his power to the setting of my doubts, but it will be clear, also, why I think the statement quoted in your annotation is unproven.—I am, etc.,

London, W.1, Nov. 22nd. JOHN FREEMAN.

ARTIFICIAL PNEUMOTHORAX

SIR,—While lecturing to the final-year medical students of Bristol, who were paying us one of their sporadic visits for a clinical demonstration, I told them that artificial pneumothorax had definitely come to stay in the treatment of pulmonary tuberculosis and certain other chest conditions, because it was based on the common-sense and world-old principle of rest. As one of the fifty members of the Tuberculosis Study Group who visited Canada and the United States at the time of the B.M.A. Winnipeg Meeting, I noticed that some of the sanatoriums in America had as large a percentage of cases on artificial pneumothorax and its sisters, phrenic evulsion and thoracoplasty, as 75 per cent., and the same percentage is common on the continent of Europe. Here we are proud if we have 25 per cent. Considering that any part of the body (except, then, say, the parotid gland) can be attacked by tuberculosis, and contemplating the still enormous death rate, the tubercle bacillus remains a terrifying organism. It seems pertinent, therefore, to ask if we are teaching tuberculosis properly in this country, so as to train the future tuberculosis officers in doing artificial pneumothorax, phrenic evulsion, thoracoplasty, and x-ray work. Until we do this the "consultant expert" and the "pseudo-sanatorium" will still flourish, and the general practitioner will still look on them with suspicion and refuse to acknowledge them (and naturally so) as proper specialists. I wonder if the link between the large London and provincial hospitals and the public tuberculosis departments is nearly as strong as it should be. Until it becomes so the anti-tuberculosis chain will never remain intact, and no proper result will accrue from the millions of pounds we are spending on this tuberculosis campaign.—I am, etc.,

Winsley Sanatorium, near Bath, November 18th. J. D. MACFIE.

NEO-HIPPOCRATISM

SIR,—The mantle of our elder statesmen—Sir William Gairdner, Sir Clifford Allbutt, and Sir William Osler—seems to have fallen on Dr. Robert Hutchison's shoulders, and his Harveian Oration stamps him as one of our masters of medicine. The culture, the erudition, the style, the good sense, and the saving humour are all there. Most striking, perhaps, is the Orator's personal recognition of the trend to-day towards the outlook of the sages of antiquity, a trend which he terms "neo-Hippocratism," and which he finds more hopeful than the feeling of therapeutic impotence engendered by the doctrines of the morbid anatomy school.

Does Dr. Hutchison in sufficient stress on [illegible] a return to the use of the same [illegible] supplied by Nature as the principal therapeutic [illegible] Hippocrates, and, for example of [illegible] to the [illegible] modern instance, Sydenham, whose [illegible] he quotes "an effort of Nature stirring within her [illegible] might to restore the part to [illegible] of the morbific matter")? As a result the [illegible] up his errors of [illegible] of [illegible]

sense should have led him to live. Writing to such a friend, Seneca, after chaffing him for no longer being able to drink his iced wine, to eat his oysters opened on the table before him, no longer to dine with officious waiters all around, heating to the desired point the various courses, tells him, with unsympathetic humour, that he will positively, by a return to nature, owe his health to his illness!

"Vitalists" the modern followers of these ancients certainly are. They believe in the power of natural immunity, and they have recourse to the simple agents of Nature—diet, exercise, bathing, sun- and air-baths, psychotherapy—rather than to the endless remedies of materia medica, of vaccines and serums. But naturism, and its logical corollary, nudism, if they had their origin and foundation in medical science, have now passed into the public domain in many countries in Europe, more especially in Germany, where for hundreds of thousands it has become an ordered system and rule of life. Freiluftbunds, or open-air clubs, exist in almost every German city, the whole movement being known as the Freikörperkultur. It is based on three sources, of greatly increasing strength since the war: the physical culture movement, the youth movement, and, most important, the Naturheilbewegung, or natural health movement. Six "Koch" schools in Berlin, recognized and encouraged by the Government, are more like colleges than schools, and give diplomas to teachers of the method after three or four years' study. Naturism, or rather nudism, its adherents believe to be the best means of rendering simple and easy the sexual education of the young, while keeping them from the morbid curiosities, the fevers of the imagination, and the errors that are at the origin of all perversion. Perhaps even Sartor Resartus does not probe the full depth of the philosophy of clothes!

Towards the end of his oration Dr. Hutchison hints at new methods of treatment, but those he speaks of are far from the province of naturism or what neo-Hippocratism should surely be. Protein shock is, of all procedures, one of the most uncertain in its effects, difficult of correct application, and not altogether free from danger. *Primum non nocere*! Blood-letting can be effectively and more pleasantly replaced by fasting and purgation. Is blood transfusion much more effective than our old friend intravenous injection of physiological salt solution? Is it because our civilization and its accompanying ailments have become so complicated that our therapeutics are so confused? "Plurimae leges corruptissima republica," said Tacitus, and the incisive phrase seems applicable to our [illegible] the rest for diseases and their remedies. Simplify life and

More than [illegible]ows!

Gairdner, whe[illegible] a generation ago, in 1888, Sir William [illegible]ion, at its meet[illegible] President of the British Medical Associa[illegible]his address, "Th[illegible]ing in Glasgow, chose as the subject of [illegible]word as "a humb[illegible]physician as naturalist," defining that [illegible]student of Nature," reverent, and exact follower and

I am, etc., [illegible]istory surely repeats itself.—

Cannes, Nov. 2nd. A. A. WARDEN.

NEO-HIPPOCRATISM AND [illegible]—OF MEDICINE [illegible]ATE CONTROL

SIR,—Perhaps the fact that in a small w[illegible]
[illegible]o popularize Greek medicine in this cou[illegible]ay I have helped [illegible]ating it into English, may be deemed suf[illegible]try, by trans[illegible]or my offering a few words here, where th[illegible]icient excuse [illegible]Hippocrates has been invoked. Dr. Robert [illegible]e name of [illegible]n his recent Harveian Oration, has voiced a do[illegible]ar Hutchison, [illegible]s now becoming somewhat general—a doubt in [illegible]inubt which [illegible]nedical methods, and particularly in those of [illegible]our present [illegible]*outrance*. He dreads the coming of crowd-ps[illegible]e research [illegible]nto medicine. "What we have to fear," he sa[illegible]sychology [illegible]"is the influence of the mass mind . . . the exploitation of discovery for commercial ends . . . the pull of the politician, the philanthropist, and the press." Owing to our myopic views, he sees a danger "that science may become suffocated in its own secretions." We are accumulating knowledge without digesting it, and a remedy for this is "one of the most pressing needs of our generation." Dr. Hutchison even goes so far as to propose a close time of five years, to enable us to assimilate what is of use in our accumulated material.

I think another prominent tendency might be added to the counts of Dr. Hutchison's indictment against our present system. This is the growth of what may be called a neo-scholasticism, a sophistical tendency to speak of "entities" or even mere words as if they were real things. This subject has been well handled by Dr. F. G. Crookshank in his Bradshaw Lecture of 1926 on "The theory of diagnosis," an address which should be in the hands of everyone who is really concerned about this serious matter. And apart from the enormous growth of uncontrolled specialism in our time, what about the growth of medical bureaucracy? Have we not here the possible beginnings of a new sacerdotalism in our profession? We are admittedly coming more and more under the State. Dr. Hutchison has perhaps not fully realized how much the system of unbridled specialism to which he objects is bound up with this subjection of medicine; possibly he hints at the danger when he mentions "the pull of the politician." Under a State system the actual practitioners (who are in touch with the patients) are necessarily subordinated to overseers and specialists (who, *ex hypothesi*, are *not* in touch with the patients). Moreover, the further the officials are from the patients, and the greater the number of these with whom they have to deal, the more do the "patients" as such tend to fade away and to become at best "diseases," and at worst entire abstractions, ciphers, Greek names, etc. So we see that neo-scholasticism, like unco-ordinated specialism, is a natural accompaniment of the subordination of medicine to the State.

Dr. Hutchison lays stress on the mental factor in disease. He should realize that treatment of the sick mind calls more than any other branch of medicine for close personal contact between doctor and patient, and that therefore the intervention of the exogenous bureaucratic machine is fraught with more peril here than elsewhere. And, further, it must never be forgotten that the official himself has a psychology, and that, however well he may begin, and however high his original qualifications may be, the further he gets away from real patients of flesh and blood, the more does his own psychological state tend to partake of the pathological. An excessive devotion to "entities" is among the milder symptoms of this neurosis, which, in its best-known forms, has been christened "departmentality."

Dr. Hutchison asks us not to expect too much from our laboratories, but to return to the observational and clinical method, which is incarnated for him in Hippocrates. He sees the organism as an essentially unified or integrated whole, and life as a constant effort of this organism to adapt itself to its environment. And, further, the environment itself is also unified; it is not a single agent, but "a constellation of conditions." Dr. Hutchison stresses the selective or critical qualities of the organism at work, picking and choosing, eliminating irrelevant matter (the Greek *perittomata*, be it said). To the extent that the organism fails to maintain its integrity or to adapt itself to its surroundings, we have disease. Thus Dr. Hutchison wants the clinician restored to his place of pre-eminence; he rightly considers that the man who only sees the detail should be subordinated to the man who has the general view. And he asks, also, for

" bridge-makers who will mediate between the laboratory and the bedside "

It will at once be seen that Dr. Hutchison's biological views are essentially the same as those expressed by Professor J. S. Haldane and Dr. A. P. Cawadias in their letters in your issues of October 24th and November 7th. Moreover, they are undoubtedly the principles of Greek medicine at its best. For there the organism (*φύσις*, physis) is the central figure of every biological operation, and its work is to adapt itself to its environment, to select therefrom what is appropriate to its own growth (*το οἰκεῖον*), while eliminating constantly what is inappropriate (*το ἀλλότριον, τα περιττωματα*). Hippocrates also extended these biological principles into sociology—for example, in his *Airs, Waters, and Places* (man and his environment, customs, etc.). Galen has carried them further in both fields, and it is probable that at the health temples or asclepieia—the sanatoriums of classical times—the same principles were applied to psychotherapy.

Greek medicine, like Greek thought generally, laid great stress on balance, on proportion (*logos*), and it is no mere verbal coincidence that a sense of humour or proportion should characterize the exponents of a humoral doctrine (*χυμοι*, humos, humor). Is not Dr. Hutchison's complaint against the " medical organism " in effect just this, that from a defective sense of humour it has failed to digest its material, to assimilate what is good in it, and to reject the irrelevant *peritomata*, with the result that these latter are now menacing its further advance?

But let me venture on a word of criticism to Dr. Hutchison himself here. He asks for bridge-builders between clinicians and laboratory workers. Is he not thereby merely demanding another class of officials? Surely the link which he desiderates is already existent in the mental constitution of the average general practitioner. Some people will assure me that State control is nothing more than " popular control," and that, therefore, the more of it we have the better. Of those others who speak from experience rather than theory some will affirm that State control, although objectionable, is inevitable, while a third and very prominent party will say " Yes, but we can counter it by trade unionism Let all us doctors combine and form a solid *bloc* against the Government, and we will force it to do our bidding " Personally I do not believe that medical trade unionism can ever get at the root of the matter. It may be necessary for some immediate adjustments—as in the panel system ; but any method whatever—be it State or counter-State—which tends to drive doctors into crowds, and does not make its primary appeal to the individual faculties of each separate practitioner, is, in my opinion, at best but a palliative, and, like other palliatives, if given too much attention, it actually retards or prevents cure by diverting men's minds from the insidious progress of the real disease

Following Dr. Hutchison's appeal, then, for a " close time " in research, I would make bold to suggest also a close time in the creation of medical officials Let us see what we can do with the material we already have in both these departments. And above all, let our slogan be " Back to the individual patient and the individual practitioner "—I am, etc.,

ARTHUR J. BROCK, M.D.

North Queensferry, Fife, Nov 15th

RICKETTSIA-LIKE BODIES IN RHEUMATIC CARDITIS

SIR,—We have examined microscopically sections of hearts from cases of rheumatic fever, and have found the Rickettsia like bodies described by J. Tertius Clarke and Mackenzie Douglas in the *Journal* of August 8th, 1931 We have also found similar bodies in hearts and other organs from non-rheumatic cases. Some of these cases have been in children of 3 and 8 weeks old, while others have been in senile hearts of patients over 70 ; in all these cases previous history of rheumatism could be excluded. We consider the cells described by Clarke and Douglas to be tissue cells of the plasma-cell type, and the Rickettsia bodies to be the granules of these plasma cells The granules stain selectively with Pappenheim's *resorcin-methyl-green-pyronin stain.*

The point we wish to emphasize is that the cells and bodies described by Clarke and Douglas, and regarded by them as Rickettsia bodies, are just as often found in non-rheumatic as in rheumatic cases, and cannot be regarded in any way as etiologically related to acute rheumatism — We are, etc.,

Obituary

JAMES THOMAS CHARLES NASH, M D

Dr. J. T. C. Nash, who died on October 8th, rendered notable service to the public health during his tenure successively of the medical officership of health of Southend-on-Sea and the county of Norfolk Born in Southern India in 1865, he commenced his medical studies at the University of Madras, but graduated M D in Edinburgh in 1899, and took the D P H Cambridge the same year Bacteriology early attracted him and he lectured on that subject and on hygiene at King's College, London He was appointed resident physician to the Brighton Fever Hospital, thence he proceeded to Southend, where he acted as medical officer of health, bacteriologist, and medical superintendent to the Borough Fever and Small Pox Hospital Dr Nash was among the first to direct attention to the peril of typhoid infection from sewage-polluted shellfish, and his insistence on the measures required to obviate such peril brought him into conflict with the local authorities In 1908 he found a more congenial environment as medical officer, tuberculosis officer, and school medical officer to the county of Norfolk. He pressed for early notification by teachers of infectious diseases in school children, the proper treatment of ringworm, and stressed the association of infantile diarrhoea with the contamination of food by the house-fly

In 1913 Dr. Nash delivered the Chadwick Lectures on " Evolution in disease," in which he illustrated from his wide practical experience what was little acknowledged at that time—namely, the mutability of bacteria and the acquisition of specificity by saprophytic organisms Dr. Nash was a captain in the R A M C Territorial Sanitary Service, and had been president of the Eastern Counties branch of the Society of Medical Officers of Health He was characterized by breadth of view steadfast adherence to principle even under obloquy and opposition coupled with much tenderness and charm, as well as a rare capacity for friendship.

Our readers will regret to learn of the death of Lady Bruce, O B E , R R C , which took place in London on November 23rd As the wife of Major-General Sir David Bruce, K C B , F R S , A M S , she was for many years very actively engaged with him in his scientific research work.

Universities and Colleges

ROYAL COLLEGE OF SURGEONS OF ENGLAND

Annual Meeting of Fellows and Members

The annual meeting of Fellows and Members of the Royal College of Surgeons was held on November 19th, under the presidency of LORD MOYNIHAN.

The PRESIDENT presented the annual report of the Council, and made a few comments upon it. Referring to the Buckston Browne benefaction, he said that Mr. Buckston Browne had since added a sum of £2,900. There was a reference in the report to the petition by osteopaths for a Royal Charter, which the Council of the College, on behalf of the College and of all the examining bodies in the United Kingdom, had taken steps to oppose, and the question was still undecided.

Dr. REDMOND ROCHE, referring to the petition by osteopaths, said that on many occasions at the annual meetings of the College he had prophesied that in the near future the Government or the Privy Council might ask the College for its opinion on some matter of great interest to the profession, and now this prophecy had been fulfilled. He suggested that, in its discussions with the Privy Council on the subject, the Council of the College should state very strongly its opinion as to the harm which might be done if such a charter were granted.

Sir E. GRAHAM-LITTLE, M.P., remarked that the first occasion on which he had spoken in the House of Commons was on an effort made by osteopaths to obtain a charter, and he believed the motion he then brought before the House was the indirect means of preventing the charter being granted. At that time the Minister of Health made a very important pronouncement to the effect that the granting of a charter to such a body as the osteopaths would not be considered at all until they received an education of the same quality as that given to medical students, and set up their own colleges, which would be supervised by proper authorities, as were other colleges. It was a mistake to suppose that the agitation was a negligible one. One of the signatories to the osteopaths' petition was the Under-Secretary for Education in the last Conservative Government, and personally he had been astonished to discover that there was a very large committee in the House of Commons formed for the express purpose of forwarding the interests of the osteopaths. The question was of greater urgency and importance than had been generally realized by the profession.

The PRESIDENT said that during the last few months the College had been more alive than any of the other licensing bodies in the kingdom in regard to the charter requested by the osteopaths. A conference of representatives of all the licensing bodies in England—except the University of London—had been held at the College on November 13th, and had agreed to send a letter to the General Medical Council urging that Council to advise the Privy Council not to recommend His Majesty to grant the petition. The Council of the College agreed with the view expressed by Sir E. Graham-Little, and would continue to take an active interest in the question.

On the motion of Dr. WARE, seconded by Dr. RICKARD LLOYD, the hearty and sincere thanks of the meeting were conveyed to Mr. Buckston Browne for his munificent gift to the College.

Sir E. GRAHAM-LITTLE then moved:

> That this forty-third annual meeting of Fellows and Members of the Royal College of Surgeons reaffirms that it is essential that Members, who constitute nine-tenths of the College, should be admitted to direct representation on the Council, especially having regard to the striking result of the poll of Members taken last year.

He said that it seemed a little anomalous that the Council should have been devoid for so long of any representatives of the Members, since they numbered 18,000 and the Fellows only 2,000. It would be agreed that the views of the practising physician and surgeon who took the conjoint diploma ought to be represented on the Council, especially when the question of the kind of training to be given to those entering the profession came forward for discussion. In the case of his own University (London) the rank and file of the graduates were given a representation of one-third on the governing body, and the result had been highly satisfactory. It was time the Council revised its attitude towards the question, for it would be in its own interests, as well as the interests of the College, if Members were represented, and would greatly increase the prestige of the College in public estimation. There could be no doubt as to the desire of Members to have such representation.

Dr. H. H. SANGUINETTI, in seconding the resolution, said that in the present democratic age the oligarchic ruling of the College was distinctly out of date. It was not suggested that the work of the Council was not in every way exemplary, but he felt that, with reference, for instance, to education, the opinions of general practitioners were worth having.

Dr. BLACKBURN, as one of the Members of the College who were not desirous of having representation on the Council, said that practically the only criticism of the policy of the College which he had heard was in regard to its examinations. He had been interested in that subject for many years, and he knew of only one educational authority which was as nearly perfect as it could be—namely, the Royal College of Surgeons.

Dr. T. WILSON PARRY said that the Members were asking for nothing revolutionary, exceptional, or extraordinary, but merely that there might be called into existence a connecting link between the Council on the one hand, and the huge army of general practitioners, embracing some 18,000 Members of the College, on the other. Some members of the Council, with every honourable and loyal feeling for the traditions of the College, had instinctive fears that if they permitted their ship to be embarked on these uncharted seas there was danger of wreck on some concealed rock. He believed that such fear was unwarranted, but as a measure of reassurance against any such contingency he suggested that, to begin with, the Members of the College should be permitted to elect one Fellow who was a bona-fide general practitioner, together with one Member, also in general practice, to represent them on the Council, and that the Fellow so elected should be in addition to, and not replace, any of the twenty-four members of the present Council. If this was found to work satisfactorily, as it certainly would, at a subsequent election, after a specified number of years, the Members should be represented by two of their own number, which, after all, was the only ideal and practical method of dealing with the case. Dr. Parry went on to point out that the College was now undertaking research work in surgery, owing to the munificence of one who, all his professional days, was a Member of the College (Mr. Buckston Browne). It was not by pathological research and experiment alone that a great success in such an undertaking could be assured. Careful and patient observation in clinical practice was as essential as work in the laboratory, and among the Members in general practice were many who, because of their ability and opportunity, could render undeniable assistance in supplementing this great work. Co-operation between these two sections would be a magnificent means of furthering this great research project.

Mr. W. MCADAM ECCLES said that he had been a member of the Council for sixteen years, and he had never heard a word from any member of the Council against a Member of the College, unless that Member had been doing what both Fellows and Members knew to be derogatory to the profession. Members had spoken that afternoon as if the College did not belong to them, and as if the Council did not belong to them, whereas the Council was really a part of the College, of which Members were also a part. It was much to be regretted that statements should be made and reiterated which implied that the Council had not the interests of the Members at heart.

Dr. MILNER said that Members must feel that the Council did not represent them. They had a sense of grievance and injustice from the lack of such representation.

The PRESIDENT said that it was true at the present moment there was no representative of general practitioners on the Council, but in recent years there had been such representatives, especially among the provincial Members. Moreover, members of Council represented general practitioners even more than they represented surgeons, for of the 2,000 Fellows of the College, only some 250 were engaged in the special practice of surgery, the remainder being in general practice, so that the bulk of the electors were general practitioners. The Council had statutory duties to perform, its obligations were officially laid down, and only by an alteration of the charter could they be altered. No matter had been so seriously or fully discussed by the Council as the representation

of Members. At the present moment there were differences of opinion in the Council, but no difference that was not perfectly honest. No man voted against such a resolution as this who did not feel that it was in the very best interests of the College that the governing body should continue in office unchanged. He begged Members not to think that the Council had the slightest disregard for them, collectively or individually, or for the position which they held as Members of the College. The Council had given the fairest possible consideration to the arguments put forward, and had come quite deliberately to the conclusion that the weight of argument was against such representation, and that it was in the best interests of the College that the charter should not be altered. He could hold out no hope to Members that that opinion would be changed in the near future, but he would lay before the Council the representations that had been made.

The resolution was then put to the meeting, and carried by 32 votes against 3.

Vicary Lecture

The Thomas Vicary Lecture on "The surgeon and old-time plague" will be delivered by Colonel W. P. Macarthur, D.S.O., M.D., at the College, Lincoln's Inn Fields, W.C., on Thursday December 10th, at 5 p.m. Fellows and Members of the College are invited to attend. Students and others who are not Fellows or Members will be admitted on presenting their visiting cards.

UNIVERSITY OF OXFORD

By decree of Convocation the degree of M.A. is to be conferred upon Richard Hartley Rose-Innes, M.B., Ch.B., F.R.C.S.Ed.

At a congregation held on November 21st the following medical degrees were conferred:

D.M.—C. R. Young, J. R. B. Hern.
B.M.—J. F. Brock, W. D. W. Brooks.

UNIVERSITY OF CAMBRIDGE

At a congregation held on November 19th the following medical degrees were conferred:

M.B., B.Ch.—R. W. McConnel, J. H. Cyriax, E. S. Stern.
M.B.—J. W. Summerhayes.

UNIVERSITY OF LONDON

It is officially announced that as the result of a consensus of opinion among representative graduates of the University the Earl of Athlone has consented to be nominated Chancellor of the University. Other nominations have been withdrawn.

The title of Professor has been conferred upon the following: *Bacteriology*: Mr. F. W. Twort, F.R.S. (Brown Animal Sanatory Institution); *Clinical Anatomy*: Dr. H. A. Harris (University College and University College Hospital).

University College Hospital

Three lectures on the history of medicine will be delivered by Dr. James Prendergast at University College Hospital Medical School on Mondays, November 30th, December 7th, and 14th, at 4.15 p.m. The subjects to be dealt with are the history of (*a*) scarlet fever, (*b*) diphtheria, and (*c*) typhoid fever. The lectures are open to all medical students of the University of London.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH

Kirk Duncanson Fellowship

The award of the Kirk Duncanson Fellowship for medical research will take place in January, 1932. It is awarded annually for one year, but may be renewed to the same beneficiary for two additional periods for one year each. The emoluments will be upwards of £150 for the first year, and about £250 and £350 for the second and third years respectively. Some preference will be given to the claims of candidates who propose to devote themselves to research in diseases of the ear, nose, and throat. Further particulars will be found in the advertisement pages of this week's issue.

SOCIETY OF APOTHECARIES OF LONDON

The following candidates have passed in the subjects indicated:

Surgery.—S. J. Bellgard, C. J. Blewett, J. Britanischski, R. N. Gillespie, L. B. Reeves, D. N. Ryalls, H. W. Toussaint.
Medicine.—R. N. Gillespie, G. Handelsman, L. B. Reeves, V. M. White.
Forensic Medicine.—R. Frankling, R. N. Gillespie, G. S. N. Hughes, A. A. Khan, J. L. King, J. T. Mozhalaparackel, C. E. Nicholson, C. A. Saugoo, F. A. Trowbridge, V. M. White, K. G. Wrigley.
Midwifery.—J. H. Beale, M. Davies, G. S. N. Hughes, J. W. V. Sheldon.

The diploma of the Society has been granted to Messrs. S. J. Bellgard, J. Britanischski, G. Handelsman, D. N. Ryalls, J. W. V. Sheldon, H. W. Toussaint, V. M. White.

Medical Notes in Parliament

[From our Parliamentary Correspondent]

The House of Commons this week passed the Statute of Westminster Bill through committee. Debates arose on the application of the means test for the unemployed. The Expiring Laws Bill passed through committee and third reading after a debate on rent restriction and factory inspection.

On November 28th the Parliamentary Medical Committee elected Dr. F. E. Fremantle chairman, Dr. A. Salter vice-chairman, Dr. Morris-Jones honorary treasurer, and Dr. A. B. Howitt honorary secretary. Dr. Salter was chairman of the committee during the last Parliament. The committee includes all the medical members of Parliament, together with Lord Dawson and Lord Moynihan. Sir George Newman addressed it on November 26th.

The National Health Insurance (Prolongation of Insurance) Bill, and the Indian Pay (Temporary Abatements) Bill, were down for second reading on November 25th. The latter proposes to authorize compulsory reductions in the pay of British members of the Indian Services.

The Abnormal Importations (Customs Duties) Act received the Royal assent on November 20th.

Ministry of Pensions

The Annual Report of the Minister of Pensions just published as a White Paper, states that at March 31st 1931, the medical staff of the Ministry numbered 122 full-time salaried medical officers. This was 23 less than in the preceding year, the decrease being accounted for by decline in the number of medical examinations and in the number of patients under treatment. Medical men employed locally as required during the year numbered 788. The Ministry has continued the practice of sending its own mental specialist to report on the condition of Service patients in mental hospitals. Contracts for medical and surgical stores continued to be made by the War Office with contractors who supplied hospitals, clinics, and medical boards direct as required.

Pensions Hospitals

Major Tryon, replying to Dr. Fremantle on November 23rd, said that the use to which the premises would be put when the Highbury Hospital, Birmingham, was vacated by the Ministry of Pensions rested with the trustees. Much of the equipment belonged to the Birmingham Pensions Hospital Committee, but such of it as belonged to the State would be taken over by the Office of Works. Alternative employment had been provided or offered to as many as possible of the members of the staff who were in the direct employment of the Ministry, including the medical superintendent. The majority of the staff, however, were employees of the Hospital Committee.

undertake to do that. Mr. HANNON asked if the Minister was aware of the valuable services rendered by these non-official servants. Major TRYON: I am well aware that their services were valuable, and I have no doubt that the committee will do its best for them.

National Health Insurance

In reply to Mr. Logan, on November 19th, Sir E. HILTON YOUNG said the cost to the Exchequer under the National Health Insurance (Prolongation of Insurance) Act, 1930, was between £80,000 and £130,000. No payments under the Act could be made until returns of the number of persons affected were received from approved societies after the end of the current year. Sir E. HILTON YOUNG told Mr. Hicks, on the same day, that a sum of £500,000 had been distributed to approved societies for the year 1930 towards the cost of excusal of arrears due to unemployment.

Replying to Mr. Rhys Davies on November 19th, Sir E. HILTON YOUNG said regulations making minor amendments in the medical benefit regulations would shortly be published and laid before Parliament. He did not think it would be found that the regulations materially affected existing relations between insurance doctors and their patients. Mr. DAVIES asked why the Minister of Health had not consulted the Consultative Committee on National Health Insurance about these regulations. Sir E. HILTON YOUNG asked Mr. Davies to see the regulations before assuming that such a consultation was required.

The B.C.G. Tragedy at Lübeck

Sir E. HILTON YOUNG, in reply to Mr. Groves on November 23rd, said that the report made to the Medical Research Council by their two representatives who visited Germany to inquire into the deaths of seventy-six infants in Lübeck, following the administration of the Calmette prophylactic tuberculosis vaccine, was a confidential one. It dealt with technical matters, which were of interest only to research workers. It was therefore not proposed to make the report public. The report did not traverse the ground of the official German inquiry, which was made by the Imperial Board of Health. The substance of the report on that inquiry was given in reply to a question on February 17th.

Leprosy in India

On November 23rd Sir SAMUEL HOARE, replying to Major Milner, said that the number of persons classified as lepers in India at the census of 1921—the latest official figure available—was 102,513, but it was probable that the number was considerably in excess of that returned. Exact figures to show progress were not available, but great advances had been made through the training of medical men, the survey of infected areas, and the opening of dispensaries. Last year the cases under treatment in the dispensaries of one province alone were more than three times as many as were being cared for in the whole of the leper institutions of India ten years ago.

Miners' Nystagmus

On November 24th Mr. ISAAC FOOT, replying to Mr. Soper, said that statistics were available for the past few years of the number of cases of miners' nystagmus in Yorkshire reported to the certifying surgeons under the Workmen's Compensation Act. Those figures showed a decrease since 1925, but with some fluctuation. The principal measures in hand for the prevention and cure of nystagmus were those to secure improved lighting in mines, and an investigation under the auspices of the Medical Research Council.

The figures furnished to Mr. Soper showed that, in 1930, 232 cases of nystagmus were reported in South Yorkshire, and 119 in West Yorkshire, being 1.09 and 1.33 respectively per 100,000 shifts worked underground. The rate for Great Britain as a whole in the same year was 1.81, compared with 1.41 in 1929 and 1.40 in 1928.

Housing in Manchester.—Sir E. HILTON YOUNG told Sir J. Nall, on November 19th, that the corporation of Manchester had recently submitted proposals for the building of over 2,000 houses, many of which were of a larger size than he thought was required. The corporation had been asked to revise its proposals so that the bulk of the houses provided could be let at a lower rent. He assured Sir J. Nall that he would inquire into an alleged discrepancy between the figures supplied by the medical officer of Manchester and those in his Department.

Rent Restriction.—Replying to Mr. Kirkwood, on November 19th, Sir E. HILTON YOUNG stated that questions relating to the future of the Rent Restrictions Acts, and the possibility of amendments to those Acts, would be considered by the Government as early as possible in the light of the recently issued report of the Departmental Committee.

Patent Medicines.—On November 24th Sir A. BEIT asked the Secretary to the Treasury if he was aware that many proprietors of patent medicines were evading the patent medicine duty by ceding their proprietary rights, at the same time retaining the protection and good will of their registered trade names. Dr. ELLIOT replied that the law provided for exemption from medicine stamp duty in favour of known, admitted, and approved remedies, when sold under certain conditions by duly qualified chemists and druggists. He was aware that certain manufacturers had taken steps, one of which was a disclaimer of proprietary rights, to bring their preparations within the scope of that exemption, but provided this was within the terms of the statute he could not interfere.

The Services

ROYAL ARMY MEDICAL COLLEGE

The following is the list of prize winners in the junior class of instruction for officers in the R.A.M.C. and I.M.S. at the Royal Army Medical College at the termination of the session on October 30th:

Lieutenant F. K. Bush, M.B., B.S., R.A.M.C., Herbert Prize (highest aggregate), Montefiore Prize (Military Surgery), Ranald Martin Prize (Tropical Medicine), De Chaumont Prize (Hygiene). Lieutenant W. R. M. Drew, M.B., B.S., B.Sc., R.A.M.C., Marshall Webb Prize (Military Medical Administration). Lieutenant J. B George, M.B., B.S., R.A.M.C., Tulloch Memorial Prize (Pathology) Lieutenant H. J. R. Thorne, M.B., B.S., I.M.S., 2nd Montefiore Prize (Military Surgery). Lieutenant M. H. Shah, M.B, B.S. (University College Hospital), I.M.S., Parkes Memorial Prize (Hygiene), Fayrer Memorial Prize (Pathology).

Lieutenant J. M. Gibbon, R.A.M.C., who died on October 26th, had qualified for the second Marshall Webb prize in military medical administration.

DEATHS IN THE SERVICES

Colonel Robert John Shaw Simpson, C.B., C.M.G., late R.A.M.C., died at Blackheath on October 28th, aged 73. He was born at Dundee on February 22nd, 1858, the eldest son of the late Mr. George Buchan Simpson of Broughty Ferry, and was educated at Edinburgh University, where he graduated as M.A. in 1878, and as M.B. and C.M. in 1882. He entered the Army as surgeon on February 3rd, 1883, passing in second, the late Major-General Sir William MacPherson heading the list. He became lieutenant-colonel after twenty years' service, colonel on September 11th, 1912, and retired on February 5th, 1913. From 1891 to 1896 he was assistant medical officer of the Royal Arsenal, Woolwich. He served in the South African war throughout 1899 to 1902, when he was staff officer to the principal medical officer, took part in operations in the Transvaal, Orange River Colony, and Cape Colony, was mentioned in dispatches in the *London Gazette* of April 16th, 1901, and received the Queen's medal with three clasps, the King's medal with two clasps, and the C.M.G. From 1905 to 1909 he was professor of tropical medicine at the R.A.M.C. College at Millbank. After his retirement he was recalled to duty in August, 1914, and throughout the war of 1914–18 served as A.D.M.S. of the Woolwich district, receiving the C.B. for his services in 1917. Since the war he had devoted much time and trouble to the Royal Lying-in Hospital in York Road, where he was chairman of the board of governors. He compiled the medical history of the South African war, for which he received the thanks of the Government. In 1895 he married Jean Mary, daughter of the late George Halley, Esq., of Broughty Ferry.

Lieutenant John Monk Gibbon, R.A.M.C., died suddenly at Queen Alexandra's Military Hospital, Millbank, on October 26th, aged 24. He was educated in Dublin, where he graduated as M.B., B.Ch., and B.A.O. in 1930, joined the R.A.M.C. as a lieutenant on probation on May 26th last, and was stationed at the R.A.M.C. College, Millbank, where he was going through the course for newly appointed officers.

Medical News

The annual dinner of the Yorkshire Association of Graduates of Glasgow University will be held in the Great Northern Hotel, Leeds, on Friday, December 4th, at 7.30 p.m. Professor Robert Muir, M.D., F.R.S., will be the chief guest of the evening. Tickets may be obtained from the honorary secretary, Dr. William MacAdam, 40, Park Square, Leeds. All graduates of the university resident in Yorkshire and adjacent districts are invited.

The twelfth annual dinner of the medical officers of No. 14 Stationary Hospital, B.E.F., will be held at the Trocadero Restaurant, Piccadilly, on Friday, December 11th. Colonel C. R. Evans, D.S.O., will be in the chair. Any member of the mess wishing to attend who has not received a notice should apply to the secretaries, Lieut.-Colonel H. M. Perry and Dr. H. L. Tidy, 39, Devonshire Place, W.1.

The twelfth of a series of dances, in aid of the Royal Medical Benevolent Fund Guild, will be organized by St. Bartholomew's Hospital and held on Friday, *December 11th, 8.30 p.m. to 12.30 a.m., in the Great* Hall of the British Medical Association, Tavistock Square, W.C. Tickets (*single 6s., double 11s.*) may be obtained from Miss Mead, the dean's office, St. Bartholomew's Hospital, *E.C.1.*

The sixty-ninth annual meeting of the Royal Surgical Aid Society will be held at the Mansion House on Tuesday next, December 1st, at 4 p.m., under the presidency of the Lord Mayor of London.

A series of lectures on "Recent advances in physiology applicable to medicine" is being arranged by the University of Durham College of Medicine at Newcastle-upon-Tyne. The first of such lectures, entitled "Some investigations in relation to medicine," will be given at the College on Friday, December 4th, at 4 p.m., by Professor Edward Mellanby, M.D., F.R.S., of the University of Sheffield. All medical practitioners in the neighbourhood are invited to attend.

A two weeks' course in infants' diseases, with special reference to nutritional disorders and dietetics, for medical officers of welfare centres and others, will be given at the Infants Hospital, Vincent Square, Westminster, S.W., *from November 30th to December 13th.* The fee for the course is £3 3s.

The Fellowship of Medicine and Post-Graduate Medical Association announces two afternoon courses from November 30th to December 12th, one at the Infants Hospital in diseases of infants (fee £3 3s.), the other at the Hospital for Diseases of the Skin, Blackfriars, in dermatology (fee £1 1s.). A free lecture will be given by Mr. Tudor Edwards on "Surgical chest diseases," at 4 p.m., on December 2nd, at the Medical Society of London, 11, Chandos Street, the last of the series being given on December 9th, by Mr. Cecil Joll, on "Goitre, with special reference to thyrotoxicosis." Free post-graduate demonstrations will be given as follows: December 1st, City of London Hospital, Victoria Park, by Mr. W. H. C. Romanis, 9.15 a.m.; December 3rd, National Hospital for Diseases of the Heart, by Dr. F. W. Price, at 3 p.m. (admission by ticket only, obtainable from the Fellowship); December 7th, at St. John's Hospital, by Dr. S. E. Dore, 6 p.m.; December 8th, Royal Northern Hospital, by Mr. Hamilton Bailey, *3.30* p.m.; *December 15th*, Royal Waterloo Hospital, by Dr. Bernard Myers, 2 p.m.; December 17th, Miller General Hospital, by Mr. Reginald Ledlie, 11 a.m. Demonstrations will be given at the Children's Heart Hospital, West Wickham, on the first Saturday of each month by Dr. Bernard Schlesinger (fee 7s. 6d. per demonstration), the Fellowship to be notified by the previous Monday morning. Copies of syllabuses from 1, Wimpole Street, W.1.

This year's Nobel Prize for chemistry has been awarded to Dr. F. Bergius and Professor C. Bosch of Heidelberg.

Major and Brevet Lieut.-Colonel A. Butler Harris, T.D., M.B., has been appointed Deputy Lieutenant for the county of Essex.

Lord Dawson of Penn has been elected a life member of the council of Cheltenham College.

The Congress of the German Society for Urology, which was to have been held this year, has been postponed to next April, when it will take place in Vienna.

The executive committee of the International Congress of Tropical Medicine has supplied the following particulars of the second congress, to be held in Amsterdam in 1932. After the regretted death of Professor C. Eijkman, Professor G. Grijns assumed the presidency of the congress. The committee, in order to meet the majority of wishes, definitely fixed the dates of the Congress as September 12th to 17th. The subjects for discussion will be as follows: (1) avitaminoses, with special reference to beri-beri; (2) leptospira and yellow fever; (3) helminths, with special reference to ankylostoma; (4) malaria, blackwater fever, protozoan blood diseases, and kala-azar. Two reporters will be invited to read papers on each subject. The inscription fee has been fixed at £1 (Dutch guilders 12.50). The general secretary is Professor Dr. E. P. Snijders, Institute of Tropical Hygiene, Amsterdam.

The October and November issue of *Acción Médica*, the new monthly organ of the medical staff of the Pirovano Hospital, Buenos Ayres, of which only two previous issues have appeared, is devoted to tuberculosis.

Dr. August Bier, professor of surgery at Berlin University, celebrated his seventieth birthday on November 24th.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are *MUSEUM* 8861, 8862, 8863, and 8864 (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Attiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Medisecra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62559 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh.*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS

Nausea and Vomiting of Pregnancy

Dr. LAWSON L. STEELE (Blyth) writes: *Could any of your readers tell me of any effective treatment of the above-named condition?* My patient has tried the usual remedies in previous pregnancies, with no benefit. The following have proved of no avail: tablets of *corpus luteum* ; ingluvin and belladonna; bismuth preparations; carminative mixtures; saline draughts; dimol. Vomiting occurs three or four times daily, but the perpetual nausea and distaste for erstwhile favourite foods are most trying.

Anal Neuralgia

Mr. F. C. PYBUS (Newcastle-on-Tyne) writes: I have been very interested in the correspondence on anal neuralgia. Some twenty years ago *I offered a paper on this subject under the* name of "nocturnal rectalgia," which was not accepted. I am still interested in the subject, and should be glad to have some further information about it, and would welcome any case histories. I have found the duplicate copy of my original paper and propose publishing it with additional details, if some of my colleagues would be good enough to write me.

Cobalt

Dr. William C. Hoffman (Glasgow) writes in reply to the query by "J. A. R. T." (November 21st, p. 971): Cobalt has frequently been used internally, especially in combination with other metals, such as copper, iron, and zinc, for various forms of anaemia. Endomin, a haematopoietic, manufactured by Messrs. Reed and Carnrick, contains 0.03 mg. of cobalt per tablet. I cannot vouch for the efficacy of cobalt as a remedy in anaemia, but it is possible that it functions as a catalytic agent in the process of enriching the blood.

Naevus

Dr. H. F. Parker (Guildford) writes: In reply to "Inquirer's" letter (November 14th, p. 927) with reference to the treatment of a V-shaped naevus on the forehead of a baby, the painless application for about twenty seconds of a moulded stick of carbon dioxide snow should cure it, leaving practically no mark. Should the naevus be of too irregular a shape for this treatment, the best alternative would be electrolysis. Naevi may enlarge rapidly, so there should be no unnecessary delay in treatment.

Income Tax

Replacement of Car

"H. G. S." bought a car in 1927 for £850, and sold it in March, 1931, for £130, when he bought a new car for £493. At that date a car similar to the one replaced would have cost £750.

*** The replacement allowance cannot exceed the actual out-of-pocket expenditure—that is, £493 − £130 = £363, and where the new car costs less than the old one this results in a loss of allowance. If the contrary is the case the increase in cost represents an addition of capital sunk in the practice, whereas in "H. G. S.'s" case a certain amount of capital has been lost; the Income Tax Acts do not allow increases in or losses of capital to be taken into account. In the case of the car which was sold without being replaced no allowance at all is due, the cost of replacement being *nil*. This case is a forcible illustration of a point we have often made in these columns—namely, that failure to claim the annual allowance for depreciation usually involves loss in the long run, especially during periods of falling prices.

Change of Employment

"A. B." was working as locumtenent or assistant from June, 1929, to April 31st, 1931, earning approximately £400 per annum. As from June 1st, 1931, he has been acting as house-physician at a hospital, his monetary remuneration being at the rate of £100 per annum. How should he be assessed for 1931–32?

*** In our opinion there was such a definite change in the nature of the employment and the basis of remuneration in June, 1931, that "A. B." is entitled to regard himself as having ceased one employment and commenced another. In that case he appears to be entitled to be assessed on the basis of his earnings for that year—that is, one-twelfth of £400 + ten-twelfths of £100—and we see no reason why he should be put to the trouble of paying on £400 and claiming repayment at the end of the financial year.

LETTERS, NOTES, ETC.

The "Medical Register"

The Registrar of the General Medical Council (44, Hallam Street, W.1) writes: I desire to remind those who find it essential to know whether a practitioner is legally qualified or not, that in order to facilitate their work the Council publishes an office edition of the *Medical Register*, printed on inexpensive paper, and bound in boards. This edition contains precisely the same names and lists as the official edition. It is issued from this office at a special charge of 10s., post free, but no copies can be issued unless they are ordered and paid for prior to December 31st. I shall be happy to send an order form upon application. The *Medical Register* is the official publication, issued under the Medical Acts, and contains the names of all legally qualified practitioners: there is no other publication which takes its place. The Council also issues each month a list of additions to, and deletions from, the *Register*. The charge for these will be furnished upon application.

Treatment of Severe Asthma

Dr. N. Garber (Schweizer Reneke, Transvaal) writes: The rarity of cases of asthma of the type mentioned below prompts me to bring it to the notice of the profession. The patient, a married woman, is 44 years of age, and has suffered from asthma for twenty years. She has had most of the known treatments: adrenaline, ephedrine, and pituitrin, tuberculin, autohaemotherapy, theocin sodium acetate, morphine, asthma powder for smoking, atropine, vaccines, etc. Following tonsillectomy (tonsils were septic) and autohaemotherapy, she improved considerably (tonsils removed at midsummer). With the advent of the cold weather she again became subject to bad attacks, lasting thirty-six to forty-eight hours. During the last twenty-four hours she has received: (1) 1 ounce of adrenaline hydrochlor. sol., 1/1,000 subcutaneously; (2) 3/4 grain morphine hydrochloride. Yet she felt no relief. To alleviate the spasm I injected 3 grains of luminal solution intramuscularly, but no relaxation occurred until ten minutes afterwards, when I chloroformed her. The luminal then commenced to take effect, and she had a fitful sleep, with slight relaxation of the bronchial spasm, for a few hours. I wonder whether this amount of treatment does not constitute a record, even if only as far as the use of the adrenaline was concerned, 1 ounce in twenty-four hours.

Age Limits

"Juvenis" writes: Can nothing be done in the matter of age limits? Recently in a short list sent to a committee there was a medical man whom I particularly wanted—older than myself, but I consider that does not matter. His age was 51. This doctor was the very one to fill the post by his experience, manner, qualifications, and appearance. Yet the committee (whose average age was far above 51) turned him down at once as being "too old." Surely there are very good admirals, generals, judges, archbishops, prime ministers, and what-not at ages of 60, 70, or 80. In a political career a man of 45 is a baby, and yet in the medical world 45 is the usual age limit for an appointment, an age when one could still be playing Rugby football. In the Services, I believe, 90 per cent. of doctors are dispensed with at 50—the prime of life of a healthy man.

Medical Art Calendar, 1932

We have received a copy of the Medical Art Calendar for 1932 from the publishing house of J. Philip Kruseman, Nassauplein 18, The Hague, Holland. Calendars are too often dull things, evil and necessary reminders of how quickly the days pass, witnesses of wasted time. The Medical Art Calendar, with its attractive reproductions in sepia of prints and paintings by Dutch artists, illustrate the length of the art of medicine in terms of the ancient art of painting, reducing to insignificance the shortness of life. The alchemist with his flasks, retorts, and learned books, and the physician with his bleeding-bowl and urine basket, are portrayed with the rich dignity that oils alone can give to a painting. A satirical print by C. Kramm (who shows marked affinities to Hogarth and Rowlandson), in which doctors and undertakers are seen leaving a wine shop and doffing their hats to two skeletons, suggests that for these life was indeed too short. The first use of liver in medicine would seem to be of ancient origin, for the Angel Gabriel "turned heart and liver of a haddock to beat the Devil," so that Tobit might marry his bride. This calendar is very good value for 6s.

Developmental Defects

Dr. A. M. Watt (house-physician, Peterborough and District Memorial Hospital) writes: In the *British Medical Journal* for October 3rd, under "Memoranda," you have published a case of transposition of viscera. In October we had, in this hospital, a child with partial transposition of viscera, and, in addition, two other developmental defects. Heart, with apex to left, but a deficient interventricular septum, and patent ductus arteriosus. Right and left lungs each had three lobes. Stomach passed to the left; duodenum passed from left to right; caecum and appendix in left iliac fossa; sigmoid colon in right iliac fossa. Spleen in right hypochondrium; gall-bladder and most of liver in left hypochondrium; left kidney lower than right. Owing to deficient interventricular septum the child was a "blue baby," and died at the age of 13 weeks.

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 45, 46, 47, 48, 49, 52, and 53 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 50 and 51.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 298.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

489 Primary Hypochromic Anaemia

Having noted recently patients with an anaemia symptomatic of *pernicious anaemia, but in whom the blood* findings were of the secondary type, W. DAMESHEK (*Amer. Journ. Med. Sci.*, October, 1931, p. 520) reports 7 such cases (6 females). Most of these gave a history of remissions and relapses of anaemia, sore tongue, gastro-intestinal symptoms, and paraesthesias. Objectively, they showed pallor without icterus, atrophied tongue, " spoon " nails, and signs of " combined system disease "; achlorhydria was also present. *Etiological factors* were absent. The blood picture was characterized by a low colour index, hypochromia, low average erythrocyte diameter, leucopenia, relative lymphocytosis, and thrombocytopenia. The sternal bone marrow revealed a marked hyperplasia despite the anaemia. A striking feature of the disease is the prompt response to large doses of iron. Dameshek terms this condition hypochromic or erythro-normoblastic anaemia ; he discusses its relation to the pernicious type, and rejects the idea that these are cases of chlorosis. He believes that this anaemia is primary or essential ; that it is related to, and may be an unusual form of, the pernicious type ; and that it is probably dependent upon inadequate gastric digestion of iron, which may cause faulty haemoglobin synthesis, and improper maturation of erythro- and normo-blasts in the bone marrow. E. S. MILLS (ibid., p. 554) also reviews this condition, and reports 23 cases. He states that the disease is confined to females, and runs a chronic course with symptoms of moderately severe anaemia. The patients showed achlorhydria, absence of etiological factors, a hypochromic blood picture, and a resistance to ordinary anaemia treatments. Iron and copper therapy was successful in 21 cases, most patients proving refractory to iron alone.

490 Bistethoscopic Binaural Auscultation

H. FABRITIUS (*Nordisk Medicinsk Tidskrift*, October 10th, 1931, p. 649) of Helsingfors explains the advantages of a stethoscope which has two chest-pieces as well as two ear-pieces. This arrangement enables the auscultator to listen at the same moment to sounds coming from more or less widely separated parts of the body. The author's investigations with this device were prompted by the collision at the end of 1930 between the passenger steamers *Arcturus* and *Oberon*. This catastrophe was largely due to the inability of the human ear to localize accurately sounds in the dark and in fog. With the help of the binaural stethoscope with two chest-pieces, one placed over the neck and the other over the stomach, it is possible, in a case of stricture of the oesophagus, to observe the time taken by swallowed fluid to reach the stomach. This device, which was independently described by Dr. F. SIMON (*Deut. med. Woch.*, February 27th, 1931), may, moreover, be employed in the auscultation of the heart in conjunction with percussion, and also in mapping out the position of the liver.

491 Acute Pulmonary Oedema in Diseases of the Circulatory System

Enumerating the various factors ascribed as causes of acute pulmonary oedema, especially left ventricular insufficiency, C. PEZZI (*Ann. de Méd.*, October, 1931, p. 249) points out that the anatomy of the pulmonary vessels has never been considered, though it is through these that the condition arises ; they can only be studied by radioscopical examinations. The radiology of the pulmonary vessels in the acute oedema occurring in mitral diseases and arterial hypertension is described. Four cases illustrative of the former, and one of the latter, are recorded. Pezzi believes that sclerosis of the pulmonary vessels, manifested by a radioscopical syndrome of pulmonary hypertension, is the anatomical condition favouring the onset of acute pulmonary oedema in the diseases mentioned. The cardiac characters of this syndrome are *dilatation of the pulmonary artery*, accentuation of its shadow, and more or less evident pulsations. The pulmonary characteristics are markedly increased volume of the hilar shadows with clear, regular contours, numerous vascular lines radiating from the hilum, and pulsations of the hilar shadows and their ramifications. Hypertension of the greater circulation showing these signs is of grave prognosis, since they indicate a predisposition to acute oedema, pulmonary apoplexy, thromboses of the pulmonary vessels, and pulmonary infarcts.

492 Immunization of Infants against Diphtheria

J. GREENGARD (*Journ. Amer. Med. Assoc.*, July 25th, 1931, p. 228) states that immunization against diphtheria, as measured by the Schick test, can be produced rapidly and safely in a high proportion of infants by the use of two 1 c.cm. injections of Ramon's diphtheria anatoxine. Complete immunity was thus rapidly obtained in 98 per cent. of 117 infants, ranging in age from 4 days to 2 years ; a large proportion of this series were found to have a negative Schick reaction two weeks after the second injection. Of 145 infants receiving the toxoid, only two older ones (aged 19 and 10 months) showed any reaction ; this was slight and lasted only 24 hours. Ramon and Helie believe that these reactions are due to a sensitivity to certain specific proteins in the toxin. In a small group in whom the persistence of immunity was tested, one case occurred in which the Schick test became positive six months after vaccination. Three cases of clinical diphtheria were encountered during the investigation ; one occurred in a vaccinated child with a succeeding negative Schick reaction. Greengard concludes that the most favourable period at which diphtheria immunization may be performed is toward the end of the first year of life ; since diphtheria toxoid gives practically no reaction at this age, he considers it to be the ideal method of immunization.

Surgery

493 Cutaneous Lymphoblastoma

W. H. GOECKERMAN and H. MONTGOMERY (*Arch. Derm. and Syph.*, September, 1931, p. 383) record two cases of cutaneous lymphoblastoma with markedly varied clinical manifestations. The first resembled mycosis fungoides in appearance, but histologically it suggested lymphosarcoma, there being malignant and destructive infiltration of the epidermis by immature cells of the lymphocytic series. The authors remark that this case would be explainable on the assumption that mycosis fungoides can develop into lymphosarcoma, but that at any rate it may be classified as a lymphoblastoma, occurring primarily in the skin ; in lymphosarcoma the epidermis is not invaded as a rule, and there is more destruction of the elastic fibres than was observable in this case. The absence of myelocytes, and the presence of a negative oxydase reaction contraindicated myelogenous leukaemia. In the second case lymphoblastoma was at once suggested, but the differential diagnosis from Hodgkin's disease, mycosis fungoides, lymphosarcoma, and the various forms of leukaemia was not possible. There was no superficial adenopathy, except nodal enlargements which might have been inflammatory and secondary to the infected ulcers. There was no splenomegaly, but the blood changes were suggestive of Hodgkin's disease, and some confirmatory evidence was obtained at the necropsy. The authors

remark that these two cases illustrate the difficulty of diagnosing many cases according to the accepted classification, and emphasize the probably close genetic relationship of the whole group. They suggest that the term lymphoblastoma is convenient until a more correct, and possibly more generally accepted term, has been devised.

494 Intra-cortical Bolting of Fractured Bones

The chief objection to the insertion of an intra-medullary bolt or peg in the treatment of fracture of a long bone is its interference with the marrow and with the formation of endosteal callus. E. JUST (*Zentrlbl. f. Chir.*, October 3rd, 1931, p. 2499) has therefore introduced a method of intra-cortical bolting. The bones are first placed in apposition, and a mark is then made in the periosteum above and below the fracture to denote the correct position of the fragments. A hole is bored in the cortical bone of each fragment, in the direction of the long axis of the bone, and about 1 cm. deep. A stout rustless wire is inserted into the hole in the less movable fragment, and the other fragment, already bored, is fitted on to the other end of the wire. It is normally advisable to use two such pegs, with two holes in each fragment. After the operation, a plaster bandage is applied to prevent undue movement. The skull can be treated in the same way after osteoplastic operations. The advantages claimed for the method are simplicity, and the small size of the foreign body used, as well as freedom from the disadvantages of the intra-medullary pegs generally employed.

495 Differential Diagnosis of Cerebral Softening and Tumour

Despite the progress that has been made in cerebral diagnosis, the differentiation between cerebral softening and tumour is difficult in some cases. Though these conditions can present identical signs, J. A. BARRÉ, O. METZGER, and J. MASSON (*Paris Méd.*, October 3rd, 1931, p. 273) believe that additional, though slight, manifestations may be caused by neoplasms. Two cases, out of a group of 6 occurring in the last two years, are recorded in support of this view. In these, post-mortem examinations revealed the presence of tumours which had been diagnosed during life as softening. In the initial period, persistent headache, Jacksonian crises or irritative symptoms, and a slight hypertension of the cerebro-spinal fluid, point to the existence of a tumour. During the stage of evolution, the persistence and increased severity of the symptoms are indicative of tumour. When the condition has fully developed, continual agitation of the limbs and whole body, and objective changes in the side which is not involved till then (exaggerated tendon and diminished or abolished abdominal reflexes, bilateral Babinski sign), occur in cases of neoplasm. Symptoms of cranial hypertension, especially papillary stasis, and hypertension of the cerebro-spinal fluid, are usually present in tumour cases. By these signs the authors have frequently avoided diagnostic errors ; should, however, doubt still exist, they believe that ventriculography should be performed.

496 Intestinal Syphilis

J. DE LA GUARDIA (*Surg., Gynecol. and Obstet.*, August, 1931, p. 221), who records an illustrative case, states that syphilis of the intestine was first described by Monteggia of Milan in 1794 and later by Cullerier in 1854. Its rarity is shown by the fact that Fraenkel found only three cases of syphilis of the small intestine in 19,000 necropsies, and Chiari only eight cases of gastro-intestinal syphilis in 243 syphilitic corpses. The lesions may be situated in any part of the small intestine, but are especially frequent in the jejunum. They may be multiple or in separate groups, and tend to encircle the lumen of the bowel, causing stenosis. They have a uniform consistency. The lesions have nothing to do with the primary ulceration, but are a new tissue formation which attacks all the intestinal layers and is localized at an early stage round the blood vessels. The cases may be classified clinically into the following four groups: (1) those with nausea, vomiting, and diarrhoea ; (2) those with definite digestive disturbances associated with pain and distress ; (3) those indicating ulcer or stenosis ; and (4) those simulating carcinoma, with palpable tumour. The author's case occurred in a man, aged 38, in whom a syphilitic ulcer of the duodenum and first part of the jejunum was found on laparotomy, in addition to a cyst of the pancreas and cholelithiasis. Complete recovery followed.

Therapeutics

497 The Toxicity of Atophan Compounds

Twenty-five fatal cases of atophan poisoning have been recorded, but it is not generally known that this drug is present in other proprietary analgesics. F. HÖGLER (*Wien. klin. Woch.*, October 2nd, 1931, p. 1246) reports four cases of poisoning by an atophan compound ; one terminated fatally. Atophan increases the uric acid excretion, but it also promotes calculus formation ; sodium bicarbonate should therefore be administered concurrently in doses of 60 to 75 grains daily. Dyspepsia, erythema, pernicious anaemia, and jaundice have followed its administration. Some writers advise that atophan should be given for three or four days, and then be discontinued for a week or ten days. Högler states the symptoms of atophan poisoning as headache, anorexia, and diarrhoea, loss of weight, jaundice, and increase of the splenic dullness, with sugar, acetone, bile pigment, cholic acids, albumin, casts, and leucocytes in the urine. The patient who died was found to have subacute yellow atrophy. Högler found that goitrous and diabetic patients did badly under atophan treatment, which is very dangerous as a prophylactic.

498 Thyroid Therapy in Thrombo-angiitis Obliterans

Since both Thompson and Wislicki have reported that thyroid administration restored the blood volume to normal in myxoedema, S. SILBERT and MAE FRIEDLANDER (*Journ. Amer. Med. Assoc.*, July 4th, 1931, p. 17) determined to try the effects of this substance in thrombo-angiitis obliterans. Thyroid extract was accordingly given in 14 typical cases of this disease, 5 of which are here recorded. A striking increase in blood volume was noted. The blood volume increased from 20 to 25 per cent. below normal to normal. On continuing the drug, a tendency to diminution in the blood volume began to appear after about eight weeks. This tendency became gradually definite, and, on withdrawal of the thyroid, a prompt fall occurred to the original blood volume figures. With the increase in blood volume, the total proteins, calcium, and cholesterol values diminished to normal, and again increased when the thyroid was stopped.

499 Treatment of Psoriasis

W. H. GOECKERMAN (*Arch. Derm. and Syph.*, September, 1931, p. 446) describes the results of his treatment of psoriasis since his previous publication in 1925. His technique consists of the application to the patches of an ointment (1 to 5 per cent.) of crude coal tar. After about 24 hours, this is almost completely washed off with olive oil, and the patches are then subjected to short doses of ultra-violet rays from a quartz lamp. The doses are given daily, beginning with one of one minute at 30 inches ; each succeeding dose is increased by half a minute on the following four or five days. Most of the patients entered hospital, but some were treated as out-patients, with minor modifications in the technique, which, however, remained the same in its essential features. In 181 cases, only three failed to respond, and of these two were exceptional in type. Forty patients suffered also from arthritis, and in about half the arthritis improved as the skin cleared up. The author stresses the general systemic nature of the disease, and puts forward no claim to cure it by the successful treatment of its skin manifestations. He does not recommend his

method, therefore, for cases with only a few patches, since other methods are probably equally effective, but he has found it to be markedly and uniformly successful in nineteen cases of exfoliative dermatitis secondary to psoriasis.

500 Treatment of Hay Fever with Pollen Vaccines

K. H. Bagge (*Ugeskrift for Laeger*, September 17th, 1931, p. 937) has treated 18 cases of hay fever between 1923 and 1929, using vaccines made from the pollen of three kinds of grass. During the first two years he used an American vaccine, but since then he has used only a Danish vaccine prepared on the lines of Coca's prescription. The strengths used were a 1 per cent., a 0.1 per cent., and a 0.01 per cent. solution, 1 c.cm. of a 0.01 per cent. solution containing 100 units; the unit was an extract of one millionth part of a gram of pollen. Before treatment was instituted, cutaneous tests were made with all three strengths, and the strongest solution almost invariably gave a positive reaction. The 0.1 solution gave a positive reaction in about every other case, and the weakest solution very seldom provoked a positive reaction. Each course included on the average fifteen injections, given subcutaneously twice a week from about April 20th till the flowering of the grasses in question began. The initial dose was, as a rule, 10 to 20 units; the final dose was 1,000 units. The amount by which the dose was increased each time depended on the reaction provoked by the last injection. The injections were often followed in a few minutes by local redness and swelling, which usually passed off in a couple of hours. A few patients developed an urticarial rash, and a slight attack of hay fever or of mild asthma. These generalized reactions began fifteen to thirty minutes after an injection, and lasted a couple of hours. Not one of the patients was rendered completely symptom-free by this treatment, but as many as 13 considered that they had derived some benefit from it. The author concludes that his prophylactic injections effected an appreciable reduction in the severity of the symptoms of hay fever in the ensuing hay fever season, but he admits that in Denmark, between 1923 and 1929, the temperature was lower and the rainfall greater in the summer than is usually the case.

501 Haemoplastin in Henoch's Purpura

S. S. Hoffmann (*Journ. Med. Assoc. of South Africa*, September 26th, 1931, p. 600) reports a case of an Indian girl, aged 10, with an infected throat, much-hypertrophied tonsils, a temperature of 101°, pulse rate 120, and multiple joint pains. The condition was taken to be an acute rheumatic polyarthritis, and she was put on salicylates. During the night the girl was seized with acute attacks of abdominal pain, accompanied by vomiting and the passage of blood in the stools. Next day, purpuric patches appeared on her face, abdomen, and limbs, indicating the correct diagnosis; 2 c.cm. of haemoplastin were injected subcutaneously, and small doses of calcium chloride given. The haemoplastin was repeated on the two following days. Recovery was uneventful except for a rather profound secondary anaemia.

Disease in Childhood

502 Cutaneous Diphtheria in the Infant

H. Stux (*Le Nourrisson*, July, 1931, p. 228) states that cutaneous diphtheria in the infant is not so rare as might be supposed, since in the course of the last five years he has seen twenty-four cases, sixteen of which were primary and eight secondary to diphtherial rhinitis. In three instances there were relapses. Cutaneous diphtheria shows a predilection for infancy and is most likely to be found in infants' homes, affecting occupants between the ages of 4 and 7 months; those with the exudative diathesis, which creates a local and possibly general predisposition, are most liable to be attacked. In eight of the author's cases there had been a recent acute infection such as influenza, dyspepsia, or some form of suppuration. Cutaneous diphtheria in the infant is quite a mild affection, being rarely accompanied by rise of temperature or complications. Its site of election is the retro-auricular groove or the fold of the neck. In the author's experience it most frequently assumed an interrriginous or ulcerative form. Bacteriological examination is necessary for the diagnosis in spite of the clinical appearance of membrane formation. Determination of the virulence of the bacilli is also very desirable. In 14 out of 15 cases examined by Stux the bacilli were virulent for guinea-pigs. The Schick test is of no diagnostic value, owing to the frequent absence of reaction peculiar to the infant's skin. On the other hand, determination of the antitoxic content of the blood may be of some assistance in the diagnosis. Serum treatment always proved very successful, the deposit usually disappearing two to five days after the injection. As regards prophylaxis, in addition to the active immunization and isolation of carriers, it is important to keep children with the exudative diathesis and intertrigo away from sources of infection.

503 Electrocardiography of School Children

C. Bruce Perry (*Arch. Dis. in Child.*, October, 1931, p. 259) reports a series of electrocardiographic investigations of normal school children, which were undertaken to serve as a control to cases of heart disease in school children. Sinus arrhythmia (following the Krumbhaar and Jenks standard) was considered present when the difference in the longest and shortest pulse periods was 0.1 second, or over. This occurred in 72 per cent. of the cases, and was very largely a factor of the pulse rate, which was high on the whole, probably due to nervousness induced by the strangeness of the instrument used. Other types of arrhythmia were rare. The P-R interval tended to be shorter than in adults; the QRS complex, it was found, might be notched or splintered in Lead III, with no clinical significance, and it was so frequently associated with an inversion of T in this lead as to be almost the normal finding. Splintering of QRS and inversion of the T wave does not occur normally in children, except in this lead. No significant age change or sex difference was recognizable in the electrocardiograms of children between the ages of 5 and 14. C. Bruce Perry (ibid., p. 265) employed clinical, radiographic, and electrocardiographic investigations in a group of cases presenting various constant physical signs, strongly suggestive of a cardiac lesion, but of a congenital rather than an acquired type, with a view to determining whether they would thus be distinguished from acquired heart disease. He concluded that there was no electrocardiogram which could be classed as characteristic of congenital morbus cordis, and that this line of examination was of little value in the diagnosis and differentiation of minor congenital cardiac abnormalities.

504 Treatment of the Broncho-pneumonia of Childhood

E. Lenstrup (*Ugeskrift for Laeger*, August 27th, 1931, p. 867) discusses the treatment of broncho-pneumonia in children in the Dronning Louises Börnehospital in Denmark, where between October, 1919, and October, 1929, he dealt with 261 cases. There were 37 deaths, or a mortality of 14 per cent. The mortality in the first year of life was barely 20 per cent., and for the first two years 16 per cent. A comparison of these results and of the treatment given with those of other hospitals was sufficiently favourable to the [illegible] hospital to make him decide to continue on the [illegible] as before. The patients were isolated as [illegible], and the nurses were trained to secure a *Special Quiet* and quiet as possible for the children, who [illegible] not awakened in order to be given medicines or [illegible] have their clothing changed. Every examination, notably the stethoscopic, was avoided unless it was absolutely necessary. A steam kettle was supplemented by oxygen inhalation when the patients were cyanosed and air-hungry. Bronchitic symptoms were treated with ipecacuanha, and in severe cases stimulants were injected four to six times in the twenty-four hours. When sedatives were indicated, chloral was given as a

gruel enema. Codeine was administered for a constant irritating cough to children over the age of 1 year. The supply of fluids was liberal, but the patients were not forced to eat much. Great care was taken to maintain the action of the bowels, laxatives being employed when necessary. The procedures which the author did not prescribe included the open-air regime, which he considered unsuitable in Copenhagen at those times of the year when broncho-pneumonia was most common in children. He also dispensed with every sort of hydropathic treatment, the quinine group of drugs, febrifuge drugs, blood-letting, blood transfusion, and every form of serotherapy.

Obstetrics and Gynaecology

505 Physical Exercises During the Puerperium

M. MERENITSCHEWSKAJA (*Zentralbl. f. Gynäk.*, October, 17th, 1931, p. 3071) illustrates the physical exercises which at a Moscow hospital the patients are taught to use from the second or third day of the puerperium. He is satisfied that they promote involution of the uterus, improve the action of the bowels and the tone of the tissues, and have a favourable effect on the cardio-vascular and haemato-poietic systems. Physical exercises are contraindicated after an operative delivery or by tears of the peritoneum, pyrexia, cardiopathy, nephropathy, or pulmonary tuberculosis. Recumbency of the trunk is maintained, but movements of the shoulders and limbs are prescribed, and the patient is allowed to lie face downwards (doing arm or leg movements) from the sixth day. The exercises are practised rhythmically and with deliberation twice daily as a rule.

506 Cancer in Women and the Climacteric

F. G. GADE (*Norsk Mag f. Laegevid.*, June, 1931, p. 593) states that a study of the Norwegian cancer statistics for the period 1919–23 shows that the mortality from cancer of the ovary, uterus, and breast is greatest about the age of 50 years—that is to say, 15 to 20 years earlier than the maximum mortality from cancer of other organs. The great majority of deaths from cancer in these situations thus closely coincides with the period of the climacteric. Comparison with the statistics of England and Wales for the period 1911 to 1926 shows that the figures from the two countries closely resemble each other. This coincidence between the climacteric and cancer of the female organs seems to suggest a biological law, and to indicate a local senility involving a predisposition for cancer, just as senility of the whole body involves a general predisposition for cancer.

507 Recurring Pre-eclamptic Toxaemia

R. D. MUSSEY (*Minnesota Med.*, October, 1931, p. 889) discusses the etiology of pre-eclamptic toxaemia, and mentions that this occurs as a primary condition in about 3 or 4 per cent. of pregnant women. It seems to cause some impairment of the patient's resistance, and is therefore liable to recur. Such recurrence may be due to lowering of the physiological defence, to sensitization of the tissues, to certain foreign proteins (perhaps elaborated in the placenta or foetus, or in both), or to actual injury of the tissues by the toxin. The kidneys appear to be specially affected, and recurrence may result from undetected renal or arterial impairment. [illegible] necruent on the first attack. In a series of cases [illegible]testinal syph the author none of the patients with eclampsia may be situated had had ante-natal care, and most of the especially pre-eclamptic toxaemia had either had no such [illegible]e or it had been inadequate. Ante-natal supervision would lower the incidence of this condition. Mussey emphasizes the importance also of post-natal care, and adds that a woman who has had pre-eclamptic toxaemia should not become pregnant again until a year or more has elapsed, and then only after estimation of the functional ability of the kidneys has revealed that they can stand the strain of pregnancy.

Pathology

508 The Value of Fixation Abscesses

R. F. LE GUYON (*C. R. Soc. de Biologie*, October 12th, 1931, p. 43) has carried out a number of experiments on laboratory animals to ascertain the value of the fixation abscess in infections with various organisms. Guinea-pigs were inoculated with 2 c.cm. of an aqueous suspension of anthrax bacilli from a 24-hour agar culture. Half of the animals served as controls; the remainder received directly after the injection 0.4 c.cm. of essence of turpentine subcutaneously. All the animals died in the same time with the same lesions. In another experiment one batch of guinea-pigs inoculated with 0.01 c.cm. of diphtheria toxin were injected with turpentine; they died in the same time as the controls in which no fixation abscess had been produced. Two batches of mice were injected with a virulent streptococcal strain, and two further batches with a virulent pneumococcus strain; some in each batch immediately afterwards received 0.2 c.cm. of turpentine. The animals in which a fixation abscess had been produced behaved similarly to those in the control group, the turpentine abscess not modifying in any way the progress of the infection. Ten guinea-pigs were injected under the skin of the thigh with 1 c.cm. of turpentine. During the formation of the abscess, the animals were given 1/100 mg. of virulent bovine tubercle bacilli subcutaneously in the abdominal region. These animals lived no longer than the control animals with no fixation abscess. Similarly rabbits with a subcutaneous fixation abscess showed no advantage over control animals when both were inoculated with 10 mg. of bovine tubercle bacilli intravenously. In none of these experiments did the fixation abscess modify the fatal evolution of the infection; the author therefore gravely doubts the therapeutic value of this method of treatment in human disease.

509 The Gastric Function of Ulcer Cases

O. B. MAKAREWIC (*Deut. med. Woch.*, October 2nd, 1931, p. 1703) states that the usual test meal is not satisfactory as a measure of gastric function, especially since the amount of acidity depends on so many factors, including the emptying time and amount of neutralization from duodenal regurgitation. He has therefore employed Lewin's method, in order to investigate separately the various functions of the stomach in 39 cases of gastric and duodenal ulcer. He finds that the amount of secretion in one hour (using Ehrmann's test-drink) is usually increased (100–300 c.cm.), and that the secretion is protracted and not sudden, as described by some authors. As a rule the amount of secretion is inversely proportional to the acidity, so that even in cases of hypochlorhydria, the total acid secreted may be excessive. The total amount of hydrochloric acid secreted is, in fact, nearly always high, and over 1 gram. The emptying time varies widely with the position and stage of ulceration. This greatly influences the acidity of the contents, as determined by the ordinary titration methods, high acidity being found usually in cases in which emptying is rapid, and vice versa. The author adds that he has not yet assessed the diagnostic value of his conclusions.

510 Endocarditis and B. coli Infection

G. BORRUSO (*Il Policlinico*, Sez. Med., October 1st, 1931, p. 511) records a fatal case in a man, aged 40, the necropsy on whom showed a streptococcal endocarditis and no other septic focus, although *B. coli* was found in blood cultures several times during life. This organism may therefore act as a secondary invader in the course of another infection, even for a considerable time before death. In the present case it was found sixteen days before death. A critical study of the literature of *B. coli* septicaemia showed that in many cases the condition was not really a septicaemia, but a bacteriaemia. Cases on record of supposed *B. coli* endocarditis are open to criticisms of various kinds, so that up to the present time the existence of this type of endocarditis cannot be admitted.

PRODUCT OF THE GLAXO LABORATORIES GL

Glucose-D

A new preparation for oral administration.

A high grade powdered medicinal glucose (98%) with Ostelin vitamin D, and an assimilable calcium-phosphorus compound, the presence of which compensate for any deficiencies in a low fat diet. For use in all cases in which glucose is indicated, such as heart disease, and many acute illnesses. May be given freely to children and adults.

1-lb. tins 1/9.

Adexolin

Vitamins A and D highly concentrated.

In acute infections Adexolin brings the temperature and pulse rate down, and also enhances resistance. Patients liable to frequently recurring colds, influenza, and to infections of the respiratory tract, benefit during the winter if Adexolin is started during the autumn.

Boxes of 25 capsules 3/9 per box.

Boxes of 100 capsules 12/6 per box.

Erbolin

ERGOT IN IDEAL FORM.

Powdered defatted ergot which is stable and retains activity for 2 years. Erbolin carries a certificate of potency, based on the physiological standardisation of the product in the Laboratories of the Pharmaceutical Society. Each capsule contains the equivalent of 0.5 mgm. (1 20 grain) ergotoxine phosphate.

Bottles of 25 capsules 3/4.

Bottles of 100 capsules 10/-.

Bottles of 500 and 1,000 also available.

B. Acnes Antivirus Ointment

For the local treatment of Acne Vulgaris.

Antivirus therapy is convenient and rapid. It increases the resistance of cells to infection. It is applicable always where direct contact between the affected tissues and the antivirus can be obtained. There are no contra-indications.

Collapsible tubes, 2 6. All our antivirus preparations bear the mark "ANTIVIRIN."

TO COUNTER ACIDOSIS

As SALVITAE contains 59% of Potassii et Sodii Citro Tartras and 30% of Sodii Sulphas it is of great value both in maintaining health and in the treatment of disease, through eliminating deleterious nitrogenous products and favourably influencing circulation, glandular secretions, peristalsis, and metabolism.

The fruit acids of SALVITAE are converted in the system into potentially basic alkaline carbonates, thus enabling the blood to keep the uric acid compounds in solution, and facilitate their removal.

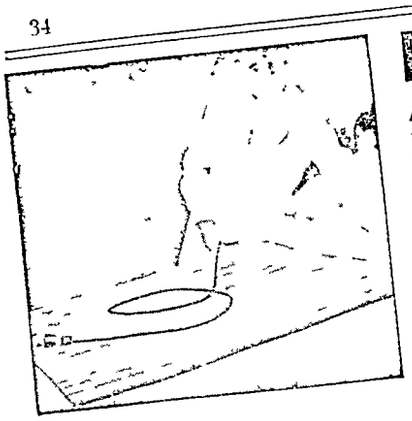
WHOOPING-COUGH



The best practice in the treatment of Whooping-cough recognizes the importance of keeping the patient out of doors as much as possible. The food should be easily digestible, nourishing, and given a little at frequent intervals.

There are no specifics for this disease. In very young children drugs are administered with difficulty and are of uncertain effect.

Vaporized Cresolene at night will be found a simple and effective means of preventing the paroxysms at that time, thus tending to preserve the strength of the patient, avoid complications, and hasten convalescence.

ALLEN & HANBURYS, LTD. :: :: Lombard Street, London, E.C.3.

BED DAMPNESS BANISHED . . . .

An important health factor, particularly at this time of the year when coughs, colds, and flu are so prevalent, is sound healthy sleep.

Thermega Electric Blankets and Pads are made for this specific purpose.

Laid flat on the bed and switched on an hour before retiring, the Blanket airs and warms the bed to body temperature. The Pad ensures LOCAL regulated heat which may be maintained as long as desired.

Both are controlled by an ordinary wall switch (any voltage, 100—250), overheating is eliminated by special thermostatic control; current costs less than a farthing an hour.

Blankets from £3 3s., Pads from 31/6d, Heating Blankets for Doctors' couches from £7. Special appliances for pneumonia, operations, etc., to order.

Further details supplied immediately on request.

PERFECT FOOTWEAR COMFORT IS GUARANTEED TO EVERY CUSTOMER!

FOR DEAFNESS

Doctors prefer "ARDENTE" because—

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises, giving inconspicuous hearing.
4. It conveys sound from varying ranges and angles.
5. It is entirely different, uncopyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf through various causes.
7. It is helpful for conversation, music, talkies, wireless, home, office, public work, and sports.

FREE HOME TESTS
arranged for Doctors and Patients.
Medical Prescriptions made up to the minutest detail.

ENGINEERING PROBLEMS IN ABDOMINAL DISPLACEMENTS SOLVED BY SURGICAL BELTS

The medical profession is beginning to realise that when it is a matter of internal displacement, abdominal disorders will not yield the stimulation or lubrication from within. These methods ignore the mechanical problems which would be the first consideration of an engineer called upon to conserve the function and structure of a coiled, mobile and valved tubing such as the alimentary system. The solving of these problems is the first consideration in the construction of Domen Belts.

These Belts correct and prevent mechanical faults in the engineering system of the abdomen by counteracting with upward support the downward pull of gravitation. And to do this Domen Belts rest upon the only anatomatically legitimate foundation—the bony pelvis. Domen Belts are designed for specific complaints. They fit well and comfortably. They leave the patient free and unembarrassed. Your card or a telephoned request will bring you full particulars.

ST. ANDREW'S HOSPITAL

FOR MENTAL DISORDERS,

NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or who wish to prevent recurrent attacks of mental trouble, temporary patients, and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms, with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

BETHLEM ROYAL HOSPITAL, for Nervous and Mental Disorders,

Monks Orchard, Monks Orchard Road, Eden Park, Beckenham, Kent.

Reg. Tel. Address: Bethlem, Beckenham. *Telephone*: Springpark 1180—1181.

Station: Eden Park (Southern Railway).

President: Lord Wakefield of Hythe, C.B.E., LL.D.
Treasurer: Sir Lionel Faudel-Phillips, Bart.
Physician-Supt.: J. G. Porter-Phillips, M.D., F.R.C.P.

This Registered Hospital is now situated at Monks Orchard, in some 250 acres of park, pleasure, and farm grounds.
Applications can be considered on behalf of patients of the educated classes in a presumably curable condition.
With a view to early treatment voluntary or uncertified patients are admitted.
Patients who can contribute 5 guineas weekly towards the cost of treatment and maintenance may be received as vacancies arise. The Committee will also consider applications for admission at lower rates, and in certain cases will be prepared to admit patients free of charge.
Every facility for specialized investigation and treatment is provided in the Lord Wakefield Science and Treatment Unit. In this Unit is found the *X*-ray and Dental Departments and the Bio-Chemical, Pathological, and Psychological Laboratories.
Furthermore, provision is made for Electro-Therapy and Hydro-Therapy to be carried out in all their forms.
In addition to the Resident Medical Staff, Consultants in special branches of Medicine and Surgery are available whenever required.
The comfort of sensitive patients is greatly enhanced by the fact that the majority are given single bedrooms.
For forms and further particulars apply to the Physician-Superintendent at the Hospital.

Royal College of Physicians of EDINBURGH.

KIRK DUNCANSON FELLOWSHIP FOR MEDICAL RESEARCH.

In accordance with the Bequest of Mrs Isabella Kirk Duncanson to commemorate the late Dr. J. J. Kirk Duncanson, the Council of the Royal College of Physicians will make an award of a Kirk Duncanson Fellowship in January, 1932. The Fellowship will be awarded annually for a period of one year. It may be renewed to the same beneficiary for two additional periods of one year each. The emoluments will be upwards of £150 for the first year, about £250 for the second year, and about £350 for the third year. In recognition of Dr Kirk Duncanson's interest in the Diseases of the Ear, Nose, and Throat, some preference will be given to the claims of candidates who propose to devote themselves to research in that branch of Medicine.

Applications and recommendations, with particulars of the special line of research contemplated and of the place where the investigations are to be conducted, should be in the hands of the Secretary of the College, 9, Queen Street, Edinburgh, by January 15th, 1932.

University of London.

British Institute of Radiology.

The Council of the British Institute of Radiology propose to appoint as from January 1st, 1932, a SUB-EDITOR to the *British Journal of Radiology*. Candidates for the appointment, which will be a full-time one, should have an acquaintance with medical radiology, a proficient knowledge of French and German, and preferably some experience in the duties relevant to the production of a scientific journal. The commencing salary will depend on the qualifications and experience of the candidate appointed, but may be assumed to be of the order of £400—£500. Applications, accompanied by particulars of qualifications, testimonials, etc., should reach the General Secretary, British Institute of Radiology, 32, Welbeck Street, London, W.1, not later than December 8th.

APPOINTMENTS.—Contd.

The King Edward VII Welsh NATIONAL MEMORIAL ASSOCIATION.

Applications are invited from duly registered Medical Practitioners for the post of AREA ASSISTANT TUBERCULOSIS PHYSICIAN. Salary £500 per annum, rising by annual increments of £25 to £700 per annum (subject to a scale of temporary deductions, which on £500 will amount to £19), together with travelling and subsistence allowances when away from base.

Preferably candidates should have had at least six months' special training in Tuberculosis, with eighteen months' experience in general clinical work, of which six months should have been spent in a Hospital not confined to the treatment of Tuberculosis. Knowledge of Welsh desirable.

The post is subject to the provisions of the Association's Superannuation Scheme, for which purpose it will be necessary for the successful candidate to pass a medical examination.

Applications, stating age, qualifications, and previous experience, together with copies of three recent testimonials, should reach the undersigned not later than December 3rd.

Memorial Offices, Westgate St., Cardiff. D. A. POWELL, Principal Medical Officer.

North Ormesby Hospital, MIDDLESBROUGH.

HOUSE PHYSICIAN required (male and unmarried). Salary £120 per annum, with board, residence, and laundry. There are three Residents, and the successful candidate will be eligible for the post of House Surgeon in due course. Applications, stating age, qualifications, previous experience (if any), with copies of three recent testimonials, should be sent to the undersigned at once.

GEORGE WATTS,
Secretary-Superintendent.

The Royal Eye and Ear Hospital, BRADFORD.

Wanted, JUNIOR HOUSE SURGEON (male). Salary £150, with board, residence, and laundry. Applications, stating qualifications, age, etc., with copies of recent testimonials, to be forwarded to the undersigned on or before December 8th.

F. BRIGGS,
Secretary-Superintendent.

Rotherham Hospital.

Wanted, HOUSE PHYSICIAN (male), qualified. Salary £180 p.a., with board, residence, and laundry, to have charge of Out-patients, administer Anaesthetics and assist Honorary Physician.

Applications, with copies of recent testimonials, to be sent to the Secretary, G. W. ROBERTS, 8, Moorgate Street, Rotherham.

London County Council.

Applications are invited for appointment to position of RESIDENT MEDICAL SUPERINTENDENT in Public Health Department for duty at BETHNAL GREEN HOSPITAL, Cambridge Road, E.2. Duties include also those of Medical Officer of Waterloo House, Waterloo Road, E.2. Person appointed will be under direction of Medical Officer of Health and must assist at other establishments under control of Council if required. Salary £1,100 a year by £50 a year to £1,350 a year, plus £50 a year for duties at Waterloo House. Unfurnished house or quarters free of rates, etc., will be provided.

Candidates must be duly qualified medical practitioners of at least five years' standing, have held appointment of House Physician or House Surgeon in a Public General Hospital, and have experience of Hospital administration.

Application forms obtainable (stamped addressed foolscap envelope necessary) from Clerk of the Council, County Hall, Westminster Bridge, S.E.1, and must be returned by December 4th. Canvassing disqualifies.

London County Council.

The LONDON COUNTY COUNCIL invites applications from Surgeons, duly qualified by experience in Diseases of the Ear, Nose and Throat, for appointment as CONSULTING LARYNGOLOGIST in its Sanatoria and Hospitals for Pulmonary Tuberculosis. The remuneration is at rate of 200 guineas a year to cover visits once a month to each of the four Hospitals, and once every two months to each of two Hospitals. Three of the Institutions are on the outskirts of London, and the other three are near Godalming, Wokingham, and Brentwood, respectively. To suit the convenience of applicants, the Council may divide the work between two Laryngologists and revise the remuneration. Appointment will be for twelve months in the first instance, and rate of remuneration and conditions of service will be subject to review by the Council.

Forms of application obtainable (stamped addressed foolscap envelope necessary) from Medical Officer of Health (Staff Division 4a), County Hall, Westminster Bridge, S.E.1, returnable by December 18th.

Canvassing disqualifies.

London County Council.

The LONDON COUNTY COUNCIL invites applications for appointment as HOUSE PHYSICIAN at LEWISHAM HOSPITAL, High Street, Lewisham, S.E. Salary £80 a year, together with board, lodging, and washing. Appointment is for six months only in the first instance. Candidates must be qualified Medical Practitioners, but need not necessarily have had previous Hospital experience. Person appointed will be required to live in the Hospital, to carry out such duties as may be assigned by Medical Superintendent and, should occasion arise, to assist at any of the other establishments under the control of the Council.

Forms of application obtainable (stamped addressed foolscap envelope necessary) from Medical Officer of Health (Staff Division 4a), County Hall, Westminster Bridge, S.E.1, returnable by December 18th. Canvassing disqualifies.

Further inquiries should be addressed to Medical Superintendent at the Hospital.

Borough of Hyde.

APPOINTMENT OF GYNAECOLOGIST.

Applications are invited for the post of Consultant Gynaecologist to the ASPLAND MATERNITY HOME, Werneth Lodge, Gee Cross, Hyde. Candidates must be on the Honorary Staff attached to one of the Maternity Hospitals connected with the Manchester Medical School.

The fees to be paid will be £5 5s. per case, including operative treatment, except as regards the Caesarean section, for which a special inclusive fee will be up to £10 10s., including a prior consultation.

Applications to be sent to the undersigned not later than Saturday, December 12th next.

Dated this 23rd day of November, 1931.

THOS. BROWNSON, Town Clerk.
Town Hall, Hyde.

Saint Mary's Hospital for WOMEN AND CHILDREN, Plaistow, E.13.

Applications are invited for the post of HONORARY DENTAL SURGEON, attendance one morning a week (at present Thursday). Candidates must be registered L.D.S., R.C.S. Eng., or similar qualification.

Applications, with copies of recent testimonials, to be sent to the undersigned as soon as possible.

A. ERNEST WILKES, Secretary.

Hampstead General and North-West London Hospital, Haverstock Hill, N.W.3

APPOINTMENT OF CASUALTY MEDICAL OFFICER

Applications are invited from unmarried registered Medical Women for the position of Casualty Medical Officer, vacant on January 1st next at the Out-patient Department of the Hospital, Rochester Street, Camden Town. The salary will be at the rate of £100 per annum, together with board, residence, etc., and the term will be for six months.

Applications to be made on a form which will be supplied by the Secretary, together with copies of not more than three testimonials, should reach the Secretary not later than noon on December 5th next.

Hampstead General and North-West London Hospital, Haverstock Hill, N.W.3

APPOINTMENT OF HOUSE SURGEON

Applications are invited from unmarried Medical Men for the appointment of House Surgeon vacant on January 1st next. The salary will be at the rate of £100 per annum, together with board residence, etc., and the term will be for six months.

Applications to be made on a form which will be supplied by the Secretary, together with copies of not more than three testimonials, should reach the Secretary not later than noon on December 5th next.

Westminster Hospital, Broad Sanctuary, S.W.1

There is an immediate vacancy for a HOUSE SURGEON to the Eye and Ear, Nose, and Throat Departments. The appointment is for six months (non-resident) and the salary is at the rate of £102 per annum. Meals are provided at the Hospital. Applications should be submitted to the Undersigned not later than Monday, November 30th.

CHARLES M. POWER, Secretary.

Yorkshire Children's Orthopaedic Hospital, Kirby Moorside, York (105 Beds)

Required a HOUSE SURGEON, to begin duties on January 1st 1932. Salary £150 per annum with board residence and laundry.

Applications with copies of recent testimonials should be sent to the Medical Superintendent on or before December 4th.

All communications to be addressed to the Branch Manager, BRITISH MEDICAL BUREAU, 33, CROSS ST., MANCHESTER

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)
(FOUNDED 1880.)

12, Stratford Place, Oxford Street, W.1.

Tele. Address: Triform, Wesdo—London.

Telephone: Mayfair {1782 1783

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION have every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUM TENENS.

Assistants and Locum Tenens can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Accounts, etc.

Practices and Partnerships for Disposal.

"ITS WEIGHT AT BIRTH WAS ONLY 4 lbs."

July 9th, 1931

Dear Sirs,

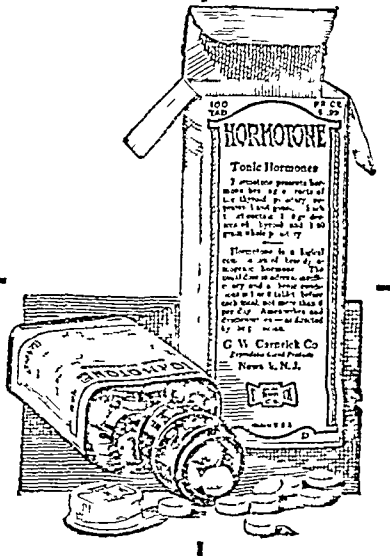
The following case will, I am sure, interest you. Baby Lowe was born on November 4th, 1929, at the 28th week. Its weight at birth was 4 lbs. It was put in an incubator and fed with a fountain-pen filler. First it was fed from the breast, then on a spray-process dried milk, and finally on a peptonised food.

It was brought to the Motherhood Bureau on June 10th, 1930—aged 7 months. Its weight was 8¾ lbs. It was still fed on peptonised feeds and could take only 4 feeds a day, and vomited after these; and was therefore losing weight.

Baby Lowe was put on a Lacidac Half Cream—4 measures to 6 ozs. of water—with Mead's Dextri Maltose No. 1, 4-hourly feeds. Within a week the sickness had improved, the baby had begun to gain a little weight, and by July 10th its weight was 9 lbs. It was then put on Full Cream Lacidac and the appropriate additions of Brestol. In August Cow & Gate Rusks were added to the diet, and mixed feeding was commenced as the teeth were beginning to erupt.

In the 5 months from July 11th, 1930, to January 7th, 1931, the child gained 8 lbs., and at the last report on May 28th, 1931, was very bonny and well and was walking and climbing everywhere.

C.M.B.



Cow & Gate Milk Food

The makers will be pleased to send clinical samples of Lacidac, which is made in three strengths—full, half and separated—and Brestol to any members of the profession who may be interested

Books—The Best Christmas Gifts

Beckman's Treatment

There is no other book like it.

"This book or its equivalent should be in the hands of every physician, and we have not yet come across its equivalent."— THE LANCET

"The publication of Professor Beckman's book on Treatment will be welcomed by medical men, and we owe a debt to him for having it introduced into England. . . . Bacon said: 'Some books are to be tasted, others are to be swallowed, and some few are to be chewed and digested. Professor Beckman's book is to be chewed and digested.'"— MEDICAL PRESS AND CIRCULAR

By HARRY BECKMAN, M.D. Professor of Pharmacology, Marquette University, Milwaukee. Octavo volume of 899 pages. Cloth, 45/- net

Recently Issued

MINOR SURGERY

Recently Issued

By FREDERICK CHRISTOPHER, M.D., F.A.C.S., Associate in Surgery, Northwestern University Medical School, Chicago. With a foreword by ALLEN B. KANAVEL, M.D., F.A.C.S., Professor of Surgery, Northwestern University Medical School. Octavo of 694 pages, with over 600 illustrations on 465 figures. Cloth, 35/- net

"This is a very good book. Its arrangement follows the usual lines except for the welcome addition of a long chapter designed for 'The Surgical Intern.' This is full of sound advice which may be read with profit, not only by the house surgeon but also by his chief, and is equally applicable to readers in our own hospitals. . . . The book is admirably printed on excellent paper and the illustrations are superb. The consulting surgeon and the practitioner will find much to interest them, while the house surgeon will find it invaluable."—THE LANCET

Fifteenth Edition

ILLUSTRATED MEDICAL DICTIONARY

Over 2,500 New Words

By W. A. NEWMAN DORLAND, A.M., M.D., Member of the Committee on Nomenclature and Classification of Diseases of the American Medical Association. Octavo of 1,427 pages, with 525 illustrations, 105 in colours. Flexible binding, 35/- net, with Thumb Index, 37/- 6d. net

"The last many days received the most thorough revision of its long career, and several thousand terms noted in the most recent medical literature have been added. . . . It may be said that the new edition fully justifies the great amount of work that has evidently been devoted to its preparation."—BRITISH MEDICAL JOURNAL

Fourth Edition

HISTORY OF MEDICINE

Recently Issued

By FIELDING H. GARRISON, M.D., Lieutenant-Colonel, Medical Corps, U.S. Army, Surgeon-General's Office, Washington, D.C. Octavo of 996 pages, with numerous portraits and other pictures. Fourth Edition. Cloth, 55/- net

"The most up-to-date and in some respects the most valuable of medical histories. The record of progress is traced through a story of human interest. The author is never dull. . . . We congratulate him on having produced a fascinating volume, as well as one full of solid learning, one, unlike most histories of medicine, to read from end to end with a zest."—PUBLIC HEALTH

Fifth Edition

OBSTETRICS

Superb Illustrations

By JOSEPH B. DE LEE, A.M., M.D. Professor of Obstetrics at the Northwestern University Medical School, Chicago. Large octavo, 1,140 pages, with 1,125 illustrations on 923 figures, 201 of them in colours. Cloth, 55/- net

"The author may be again congratulated on what is truly a monumental work. The text is lucid, and the illustrations are excellent. . . . It would be difficult to find a more complete description."—BRITISH MEDICAL JOURNAL

W. B. SAUNDERS COMPANY Ltd. 9, Henrietta Street LONDON, W.C.2.

APPROVED LABORATORY TECHNIC

JOHN A. KOLMER, F. BOERNER, and Contributors.

Clinical, Pathological, Bacteriological, Serological, Biochemical, Histological. With eleven coloured plates and three hundred illustrations in the text. 663 pages. Cloth. (Just Issued.) 30s.

GYNAECOLOGICAL AND OBSTETRICAL PATHOLOGY

ROBERT T. FRANK, M.D.

Includes chapters on the Normal Histology and the Physiology of the Female Genital Tract and the Peritoneum. Outstanding features of the book are the bibliography at the end of each chapter and the 423 Illustrations. 30s.

BIRTH INJURIES OF THE CHILD

HUGO EHRENFEST, M.D.

"Contains a vast amount of material which will be of interest to the obstetrician, the paediatrist, and the neurologist alike. The author's painstaking correlation of a mass of evidence has placed the subject of birth trauma on a more scientific basis than has hitherto been reached."—Lancet. 25s.

PRINCIPLES OF PATHOLOGY

H. D'ARCY POWER, M.D., and WILLIAM W. HALA, M.D.

Lays stress throughout on the functional derangements that are the cause of, and are caused by, disease processes. 787 pages, with 293 illustrations, many of them in colour. 42s.

A SURGICAL DIAGNOSIS

J. L. DONHAUSER, M.D.

"He has produced a book of sound surgical teaching and attacks the problems of diagnosis in a way that is both original and satisfactory."—Lancet. With 35 illustrations and many charts. 42s.

D. APPLETON & CO. 34, BEDFORD STREET LONDON

LIPPINCOTT BOOKS

Monographs on Surgical Pathology.

SURGICAL PATHOLOGY OF THE GENITO-URINARY ORGANS

By ARTHUR E. HERTZLER, M.D. 222 Illus. 21s.

In this book the author has presented the subject from the viewpoint of the general surgeon. OTHER VOLUMES TO FOLLOW.

BRAIN AND SPINAL CORD

A Manual for the Study of the Morphology and Fibre-Tracts of the Central Nervous System

By EMIL VILLIGER, M.D., of the University of Basel. Edited by WILLIAM H. F. ADDISON, M.D. 262 Illustrations, many in colours.
Fourth Edition. Ready shortly. 25s.

A lucid, concise, and up-to-date synopsis of the anatomy of the central nervous system.

TEXTBOOK OF UROLOGY

For Students and Practitioners

By DANIEL N. EISENDRATH, M.D., and HARRY C. ROLNICK, M.D. 700 Black and White Illustrations and 11 in Colour. Second Edition. 42s.

"The book is admirably produced, and contains seven hundred illustrations in black and white, and eleven in colour, many of them really beautiful."—THE PRACTITIONER.

PHYSICAL AND CLINICAL DIAGNOSIS

By Dr. OTTO SEIFERT and Dr. FRIEDRICH MUELLER. Authorised translation from the 24th German edition by E. COWLES ANDRUS, M.D. 140 Illustrations and 3 coloured inserts. 25s.

EVERYDAY PRACTICE SERIES.

Edited by HARLOW BROOKS, M.D. A new volume. Ready shortly. 21s.
Bound in flexible, imitation leather.

ORTHOPAEDICS IN CHILDHOOD

By W. L. SNEED, M.D.

This volume gives the actual results of the work of the author.

HUMAN PATHOLOGY: A Textbook

By HOWARD T. KARSNER, M.D. With an Introduction by SIMON FLEXNER, M.D. 463 Illus.
Third Edition Revised. Ready shortly. 45s.

"Prof. Karsner's text-book is a notable addition to pathological literature, the teaching is sound and orthodox, and the subject is treated in the widest sense. . . ."—THE LANCET.

LIPPINCOTT'S QUICK REFERENCE BOOK FOR MEDICINE AND SURGERY

By GEORGE E. REHBERGER, A.B., M.D.
Seventh Edition. 3 Folding Manikins. 33 Coloured Plates. 151 Illustrations. 65s.

Covers the whole field of practical medicine excepting Psychiatry.

"This is the ideal book for the one-book medical practitioner. In it he will find almost anything that he could possibly want to know."—THE INDIAN MEDICAL GAZETTE.

HUMAN ANATOMY

Including Structure and Development and Practical Considerations

By GEORGE A. PIERSOL, M.D., and others.
Ninth Edition. 1,734 Illus., 541 in colour. 45s.

The latest, best, and most richly illustrated Anatomy published.

Medical Catalogue sent post free on application.

J. B. LIPPINCOTT COMPANY, 16, John Street, Adelphi, London, W.C.2.

BAILLIÈRE, TINDALL & COX

"Accepted as an epitome of current medical views."—BRITISH MEDICAL JOURNAL.

ROUTLEDGE KEGAN PAUL

THE GENESIS OF CANCER

By W. S. HANDLEY, M.S., F.R.C.S.

With 113 Illustrations. 21s. net.

The author, who is senior Surgeon to the Middlesex Hospital, infers that local lymph stasis is a constant precursory factor in malignant disease, and here presents the evidence for this inference. His view is that the pathology of papilloma is the clue to the origin of cancer.

PHANTASTICA: NARCOTIC AND STIMULATING DRUGS

By L. LEWIN. 15s. net.

Dr. Lewin deals in turn with Euphorica, Phantastica, Hypnotica, and Excitantia. The book is a lucid study of narcomania in civilized countries.

PHYLAXIS

By G. BILLARD, M.D, 9s. net.

Professor Billard's hitherto unpublished researches into the use of such agents as sparteine, chloroform, certain mineral waters, etc., against various toxins.

THE MIND AND ITS BODY

By CHARLES FOX. 10s. 6d. net.

The author deals with the reaction of the mind to the body in the light of the new knowledge acquired by physical, physiological, and psychological research.

THE CONQUEST OF OLD AGE

By P. SCHMIDT, M.D. 21s. net.

The author worked for eight years in the application of Steinach's theories to human beings. He is strictly objective in his treatment of the subject, and his photographs afford striking corroboration of his thesis.

BROADWAY HOUSE, 68-74, CARTER LANE, LONDON, E.C.4.

FOURTH EDITION (completing 45,000 copies). Fully Revised. Sup. Roy. 8vo. 1,180 pp. in flexible Covers. £3 3s. net, postage 1s. With 701 Illustrations, 179 of which are fully coloured, and a unique General Index of over 90,000 References.

AN INDEX OF

DIFFERENTIAL DIAGNOSIS OF MAIN SYMPTOMS

By Twenty Representative Contributors.

Edited by

HERBERT FRENCH, C.V.O., C.B.E., M.A., M.D.Oxon., F.R.C.P.

Consulting Physician to Guy's Hospital.

This work is of practical utility to medical men whenever difficulty arises in deciding the precise cause of any particular symptom of which a patient may complain. It covers the whole ground of Medicine, Surgery, Gynaecology, Ophthalmology, Dermatology, and Neurology.

"Both authors and publishers deserve great praise for producing a volume which in substance brings the highest credit to British medicine, and in format holds its own with the most lavish of transatlantic productions."—BRITISH MEDICAL JOURNAL.

"The fund of knowledge contained in this volume is incalculable . . . admirably illustrated."—LANCET.

"Beyond question a *tour de force* . . . will be found a friend in need at all times."—PRACTITIONER.

JUST PUBLISHED. TENTH EDITION. Fully revised and many New Articles. 93 Illustrations. Bevelled Boards, Burnished Top. Sup. Roy. 8vo, 1,042 pp. 42s. net; postage 1s.

INDEX OF TREATMENT

A Complete Guide to Treatment in a form convenient for reference.

Edited by ROBERT HUTCHISON, M.D., F.R.C.P.,

Physician to the London Hospital, and to the Hospital for Sick Children, Great Ormond Street, London.

In conjunction with 90 Representative Authors.

FROM PRESS NOTICES OF FORMER EDITIONS:—

"We cannot do more than recommend it in terms of high laudation; it is a volume that should be in the hands of every practitioner of medicine."—*British Medical Journal.*

"Since we first reviewed this book on its appearance in 1908 seven further editions have been issued—a gratifying evidence of success which establishes it beyond the reach of criticism. Its general plan and high standard of excellence are doubtless well known to our readers."—*Lancet.*

"This index is well worthy of its success, reflecting as it does the latest teaching in medical science."—*Medical Press and Circular.*

1930—1931 New Books

ABDOMINAL PAIN

By **John Morley**, ChM, FRCS Hon Consulting Surgeon Arbroath Hospital Manchester, Hon Assistant Surgeon, Manchester Royal Infirmary, etc With an Introduction by Professor J S B Stopford, CBE, MD, FRS
Demy 8vo 238 pp 22 Illustrations Price **10s 6d** net Postage 6d

"The impression left on the mind of the reader by this exceedingly interesting monograph is that no one special or general practitioner in active work can afford to be ignorant of the questions raised, as each in his own sphere will be the one more often than not called upon to give clinical observations supplemented, as occasion arises by examination or post mortem examination."

Just Published

AN INTRODUCTION TO HYGIENE

By **W Robertson**, MD DPH, FFCP(E) formerly MOH Edinburgh Lecturer on Public Health School of Medicine, Royal College Edinburgh Examiner in Public Health, Conjoint Board Scotland
Crown 8vo 200 pp 32 Illustrations Price **6s** net Post 4d

"This book provides the student with all the essentials of the subject under the class and examination purposes."

CHRONIC ARTHRITIS AND RHEUMATOID AFFECTIONS

By **B L Wyatt**, MD, Director, The Wyatt Clinic, Tucson, Arizona
Demy 8vo, 176 pp Price **15s** net Postage 6d

"It is generally stated that Chronic Arthritis and Rheumatoid conditions rank as the leading causes of illness. Every practitioner has examples of numerous cases and this book should inspire him in efforts to aid such patients."

A HANDBOOK OF THERAPEUTICS

By **David Campbell** MA, MD (Glas) Professor of Materia Medica and Therapeutics University of Aberdeen, etc
Crown 8vo, 432 pp 72 Illustrations Price **12s 6d** net Post 6d

"This is a comprehensive treatise on therapeutics full of up-to-date information given in a concise form. It is an excellent book for every medical student to read during his final year, while no better present could be made to a young graduate about to take up the post of house physician, or to begin as an assistant in general practice."

A HANDBOOK OF DISEASES OF CHILDREN

By **Bruce Williamson**, MD (Edin) MRCP (Lond.), Physician, Royal Northern Hospital, etc 300 pp 50 Illustrations
Price **10s 6d** net Postage 6d

"The author has provided an attractive and distinctive book. Indeed the completeness with which each subject is dealt makes one wonder why the writers of text books require so much more space. The author shows that he has given the subject much original thought and has not been content to make his book a mere condensation of larger works. The illustrations have been carefully chosen and an appendix contains a list of well tried prescriptions with some notes on the use of important drugs. It is the shortest comprehensive book on the subject yet published in English."

THE IMPROVED PROPHYLACTIC METHOD IN THE TREATMENT OF ECLAMPSIA

By **Professor W. Stroganoff**, Hon Fellow of the Obstetrical and Gynaecological Societies of Edinburgh, Belgium, Leningrad and Moscow *First English Edition*
Demy 8vo 163 pp Price **10s 6d** net Inland Postage 6d

"Everyone who practises midwifery should possess a copy of this book containing as it does a clear exposition of the prophylactic treatment of eclampsia inverted advocated and practised by Professor Stroganoff, a treatment which has led to the lowest death rate obtained by any practitioner over a large series of cases."

HYGIENE FOR NURSES

By **John Guy**, MD, DPH (Camb) MOH and Tuberculosis Officer City of Edinburgh, and **C J J Livingstone** MD DPH, Assistant Medical Officer and Tuberculosis Officer City of Edinburgh
Crown 8vo, 212 pp 18 Illustrations Price **5s** net Postage 4d

"There are many books on Hygiene, but few which adequately supply the requisite knowledge for nurses preparing to enter the state examination.

The book is clearly written and illustrated and can be thoroughly commended to those who are wishing to pass the above examination."

AN INTRODUCTION TO MEDICAL HISTORY AND CASE-TAKING

By **Geoffrey Bourne**, MD (Lond.) FRCP, Demonstrator of Practical Medicine and Assistant Physician Barts Hospital etc
Crown 8vo, 200 pp Illustrated Price **6s** net Postage 5d

"This book is an example of how much the text of a book may surpass its title for it contains much more than an introduction on Diagnosis, Prognosis and Treatment."

CLINICAL CHEMISTRY IN PRACTICAL MEDICINE

By **C. P. Stewart**, PhD (Edin), MSc (Dunelm), Senior Biochemist, Royal Infirmary, Edinburgh, etc and **D M Dunlop**, BA (Oxon), MD (Edin), MRCPE, Physiological Assistant, Department of Therapeutics University, Edinburgh
Crown 8vo, 250 pp 24 Illustrations Price 7s 6d net Post 5d.

"This book can be recommended to all senior students and practitioners, especially those engaged in hospital work. It will greatly help those who read it to understand a subject which is badly taught and very imperfectly grasped by those with only an ordinary medical training."

TEXTBOOK OF HYGIENE

By **J. R. Currie**, MA (Oxon), MD (Glas), MA, MPCP (Edin.), Professor of Public Health, University of Glasgow
Demy 8vo, 900 pp 111 Illustrations Price **27s. net** Post 9d.

"This book has been written with a stimulating freshness of treatment and contains a great mass of information much of which is not generally to be found in textbooks of the kind. It has the additional advantage of giving the Public Health laws and regulations both of Scotland and England. The book is written for students of hygiene and will be found an excellent textbook for candidates of the DPH Examinations."

A MANUAL OF TUBERCULOSIS FOR NURSES

By **E Ashworth Underwood** MA, BSc, MB, DPH (Glas) Dep MOH and Tuberculosis Officer, County Borough of Tynemouth, etc
Crown 8vo 272 pp 30 Illustrations Price **6s 6d.** net Post 5d

"The author has provided an outstanding work in view of the fact that it is the only book at present published for nurses which deals with all aspects of tuberculosis and contains the information necessary for examinations.

It is a work which should be read by all those holding offices and medical superintendents of Sanatoria who are expected not only to assist in the training of nurses, but to give them sound and helpful instruction for patients."

1931 New Editions

ANTE-NATAL CARE

Including Abnormalities in Pregnancy, with a Section on Post Natal Care

By **W F. T. Haultain**, MB (Camb), FRCSE, and **E. Chalmers Fahmy**, MB (Edin), FICSE *Second Edition*
Crown 8vo, 140 pp Illustrated Price **5s.** net Postage 4d

"The second edition has been enlarged by the inclusion of a description of the Aschheim Zondek test for pregnancy, by the insertion of a short chapter on maternity and National Health benefit and by the addition of a chapter on Post Natal Care. It is a book which should be read and studied by every medical student and practitioner."

A TEXTBOOK OF MEDICAL JURISPRUDENCE AND TOXICOLOGY

Adopted as a Textbook by H.M. Government

By **Prof John Glaister**, MD, DPH (Camb) FRSE, University of Glasgow, in collaboration with Prof JOHN GLAISTER, Jun., DSc, MD (Glas), University of Egypt, Cairo, etc *Fifth Edition*
Demy 8vo, cloth 970 pp With 132 Illustrations and 7 Plates
Price **30s** net Postage 9d

"The new edition of this textbook has the added advantage of the collaboration of Professor John Glaister, Jr., DSc, MD until recently Professor of Forensic Medicine in the University of Egypt (Cairo). The success of this textbook has been striking. It has been adopted by H.M. Stationery Office and by the Education Department of the Egyptian Government and it is used in the Law Courts as an authority on Medical Jurisprudence and Toxicology."

A TEXTBOOK OF PATHOLOGY. (Delafield and Prudden.)

Revised by **Francis Carter Wood**, MD, *Director of the Pathological Department of St Luke's Hospital New York* 15th Edition
Imp 8vo 1340 pp With 20 full page Plates and 230 Text Illustrations Price **55s** net Postage 1s

"The number of editions through which this textbook has passed testifies to the great popularity of the work. We can confidently state that there is no other book on the subject which provides the student with so fully detailed a text and with such an elaborately illustrated work."

Just Published

A HANDBOOK OF SKIN DISEASES

By **Frederick Gardiner**, MD, FSc FRCS (E), FRSE, *Lecturer on Skin Diseases Universities of Edinburgh, Physician for Diseases of the Skin Royal Infirmary, Edinburgh. Third Edition*
Crown 8vo, 300 pp 52 text Illustrations, 15 Coloured Plates
Price **10s 6d** net Postage 6d

"This book contains the happy combination of excellent illustrations which are so useful a study of the subject and a text which is eminently readable. It is a thoroughly useful book having a simple classification, diagnosis and complete full of the detail required for accurate diagnosis and successful treatment. The new edition can now be held as a final text and illustrations."

AN INTRODUCTION TO PRACTICAL BACTERIOLOGY

By **Prof. T. J Mackie**, MD (Glas) DPH (Oxford) and **J E McCartney**, MD, DSc (Edin) *Third Edition*
Crown 8vo 440 pp Illustrated with 8 Diagrams Price **10s 6d** net Postage 6d

"The new edition of this book once again emphasises the words in the authors have managed to compress a large amount of useful knowledge into a small space. It is a book with a wide range of use for students and practitioners, so called that contains a deal of information."

PRACTICAL METHODS IN THE DIAGNOSIS AND TREATMENT OF VENEREAL DISEASES

By **David Lees**, MA, MB FRCS Surgeon in Charge of Venereal Diseases Royal Infirmary, Edinburgh, and Lecturer on Venereal Diseases
Crown 8vo 650 pp With 87 Illustrations and 4 Plates Price 15s net Postage 6d

"The most important addition to the new edition is a separate chapter on cardiovascular Syphilis and the extra space devoted to various sections dealing with Neuro-Syphilis. The remainder of the book has been revised to the date of publication.

It remains a reliable text book of Venereal Diseases and the reviewer is of opinion that it is one of the best works on the subject that has appeared in the English language."

From EDWARD ARNOLD & CO.'S List

Large Imp. 8vo (12in. × 8in.). viii + 596 pp., 496 Illustrations and 18 Coloured Plates. 50/- net.

TUMOURS of the BREAST

Their Pathology, Symptoms, Diagnosis, and Treatment

By Sir G. LENTHAL CHEATLE, K.C.B., C.V.O. F.R.C.S., Consulting Surgeon, King's College Hospital; and MAX CUTLER, M.D., Director of the Tumour Clinic, Michael Reese Hospital, Chicago.

This splendid volume presents a combined clinical and pathological study based on over thirty years' experience using the method of cutting and examining microscopically serial sections of the whole breast. The researches it embodies have earned for Sir Lenthal Cheatle the Walker Prize of the Royal College of Surgeons of England. Its magnificent illustrations, with their descriptions, render the book an atlas as well as an invaluable work of reference.

A detailed illustrated prospectus is available.

THE CAUSE OF CANCER

By **W. E. GYE**, M.D., and **W. J. PURDY**, M.B.

Members of the Scientific Staff of the National Institute for Medical Research, London.

Since he published the results of his researches into the cause of Cancer, six years ago, Dr. Gye, with the collaboration of Dr. Purdy, has repeated and amplified his experiments and has discovered new facts which, he holds, support the contention that cancer is a cell reaction to a living intracellular virus. These experiments are described in detail in the present work, with an abundance of elucidatory diagrams.

The Authors devote their first section to a lucid and trenchant discussion of the problem of malignancy. The last section consists of a general review of the whole question of cancer causation.

Crown 4to. 530 pages. With 105 Diagrams. 30s. net.

MODERN MEDICAL TREATMENT

By **E. BELLINGHAM-SMITH**, M.D., F.R.C.P.Lond., and **ANTHONY FEILING**, M.D.Cantab., F.R.C.P.Lond.

With an Introduction by **Sir HUMPHRY ROLLESTON**, Bart., G.C.V.O., K.C.B.

While doing justice to the older methods of treatment the Authors have included all the recent advances in therapeutics which they have found serviceable. In his Introduction Sir Humphry Rolleston speaks of Modern Medical Treatment as an "attractive" work, "most conveniently planned for the reader's benefit."

"Should prove a valuable addition to the practitioners' library."—LANCET.

"The book is admirable. It is full of practical details regarding treatment, and illustrated with numerous prescriptions which will be of great use to students and practitioners."—CLINICAL JOURNAL.

Two Volumes, Demy 8vo. 1,432 pages. 30s. net the set.

RADIOLOGY IN RELATION TO MEDICAL JURISPRUDENCE

By **S. GILBERT SCOTT**, M.R.C.S., L.R.C.P., D.M.R. & E.Cantab.

Dr. Gilbert Scott's aim is to help those who have to deal with claims for compensation for injuries, whether as radiologists, as medical witnesses, or as counsel. His book is based upon the material that passed through his hands as Director of the Radiological Department of the London Hospital. The text is elucidated by twenty-four beautifully reproduced radiographs.

Demy 8vo. 76 pages. With 24 Radiographic Plates. 7s. 6d. net.

RADIUM THERAPY: PRINCIPLES AND PRACTICE

By **G. E. BIRKETT**, M.C., B.A.Cantab., M.R.C.S.Eng.

CALCUTTA, BOMBAY MADRAS RANGOON LAHORE, COLOMBO

To the Doctor's Wife:

Are there Dangerous Curves Ahead for YOU?

Probably the dangerous curve that troubles most women is the bulging diaphragm or the protruding abdomen. This always shews a condition of relaxed muscles which allows the stomach or abdominal organs to droop and sag. It may be caused by incorrect posture, by careless reducing methods, or by wearing foundation garments that do not give proper support. In any case, it can be entirely overcome by wearing a SPENCER designed to meet the individual requirements.

Then there is the curve that is most dangerous to the slim beauty of this season's frocks—the bulging curve of prominent hips. This may be due to an accumulation of fat around the hips, or a spreading of the hips. In any case, it can only be corrected by a garment designed to meet the specific needs of the individual.

But, probably, the curve that is most dangerous to health as well as to beauty is one that women seldom realize they have. This is an in-curve in the back at the waistline, called by physicians the lordosis curve, which causes the lower back and hips to look too full. This not only destroys the beauty of the backline, but it disturbs sensitive nerve centres which frequently cause nervousness and backaches. SPENCER designers have made a special study of this condition so that they create a garment which will be entirely comfortable and give you a normal beautiful backline.

Have a Spencer Corsetière Make a Free Study of Your Figure.

This study will be made at your home without any obligation to you, and will give you interesting information about how to prevent any "dangerous curves" that might be ahead for you.

If You Have a Figure Problem . . . .

If you have a special problem concerning the control or slenderizing of your figure, write to our SERVICE DEPT., enclosing this coupon. They will give you their expert advice free.

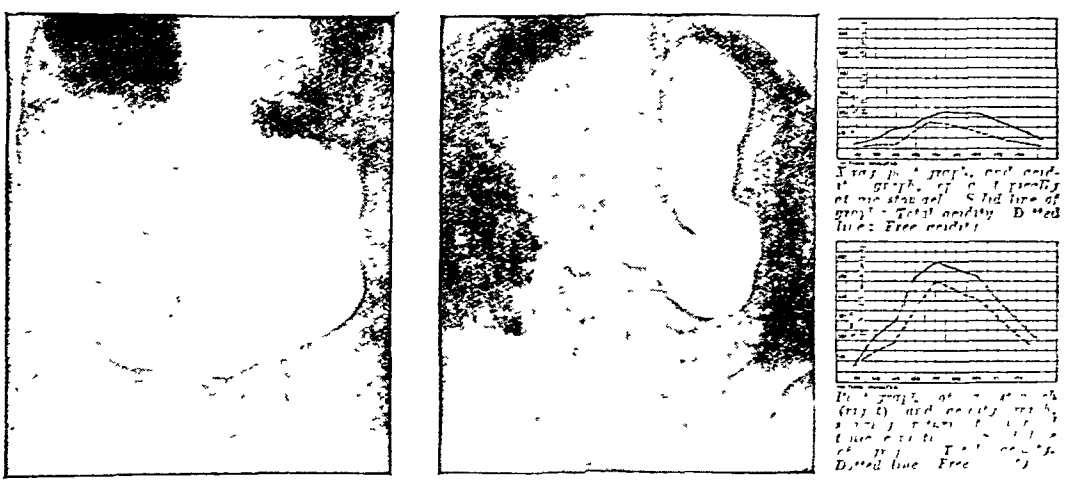
WHY IT IS PRESCRIBED FOR GASTRIC PATIENTS

When ordinary tea is out of the question it is essential that only really good China should be drunk. The Doctor's China Tea has won the enthusiastic approval of practitioners simply because it is a perfect blend of a good China leaf with all excess tannin eliminated. It can therefore be prescribed for invalids and dyspeptics with safety—it has no ill after-effects.



THE DOCTORS CHINA TEA

Priced at 3 - and 3/8 per lb.
A super quality at 4/2 per lb.

XMAS AND NEW YEAR GIFTS

Special terms will be quoted to Medical Practitioners (only) for the supply of The Doctor's China Tea in post free parcels to any address. There is nothing so acceptable as Fine China Tea.

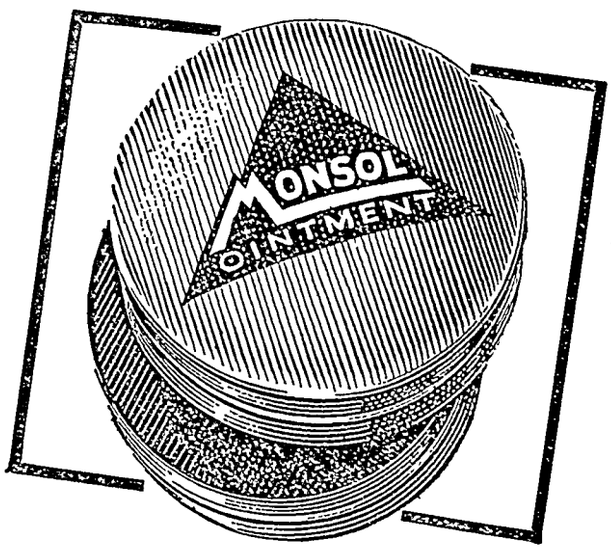
A Dependable Tonic
For administration in all cases of
Blood Impoverishment

As Liver Extract B.D.H. is prescribed as a matter of routine in pernicious anaemia, so Livogen is becoming the product of choice in the treatment of secondary anaemias such as the anaemias of pregnancy. Livogen acts, also, as a revitalising tonic in convalescence. Livogen contains not only all the essential therapeutic principles of fresh liver, including Vitamin B_1, but, in addition, a measured proportion of Vitamins B_1 and B_2 and of haemoglobin. Livogen is extremely palatable and simple of administration—it can be taken neat or diluted with water.



Livogen is available from the principal pharmacists, in bottles of 4 fluid ounces, also in bulk packages for dispensing purposes.

• • PRESCRIBE

MONSOL

BRAND

for the treatment of

LACERATED, CONTUSED or SEPTIC WOUNDS —

Monsol Liquid Germicide owes its efficiency to the fact that its ratio of germicidal power to irritant action on living tissue is higher than for any known antiseptic of its class, and that it has a selective action on gram-positive organisms.

Monsol Ointment contains the active principle of Monsol in a colloidal state in a bland and readily absorbed base, and is therefore an ideal wound dressing. Germicidally potent, penetrating and non-destructive to tissues, it facilitates the rapid formation of healthy granulation surfaces.

Samples for clinical trial from :—

THE MOND STAFFORDSHIRE REFINING CO., LTD., ABBEY HOUSE, WESTMINSTER, S.W.1

The perfect LOCAL ANAESTHETIC *at last . . .*

SELF-STERILISING. Novutox Local Anaesthetic is autogenously sterile and actually remains sterile for weeks after an ampoule or bottle is opened. Novutox can be stored in and used direct from a bottle, thus eliminating waste and economising both time and money.

• • • NOVUTOX BRAND LOCAL ANAESTHETIC can be safely injected into infected infiltrated areas.

• Read this extract from a letter recently received from a well-known surgeon:—

"I have been using Novutox for lid operations and for paralysis of the orticularis in intraocular operations and have found it quite satisfactory."
M.A., B.Ch., M.B., F.R.C.S.

1. Is seven times less toxic than cocaine.
2. Promotes quick and clean healing.
3. Ensures freedom from post-operative pains.
4. Gives deep and lasting anaesthesia.
5. Requires no preparation of any description.

NOVUTOX

ORAL MEDICATION IN URINARY DISORDERS

Pyridium given by mouth in the form of 0.1 gram tablets is of distinct service to the general practitioner as a Urinary Antiseptic and will greatly enhance the value of the usual local measures in the treatment of cocci, B. Coli, and mixed infections. Pyridium, which is non-toxic and non-irritative in medicinal dosage, is early and gradually excreted in sufficient strength in the urine to exert a bactericidal antiseptic effect, and by its selective action upon the submucous area renders it impervious to therapeutic agents. Cystitis, pyelitis, urethritis, vaginitis, cervicitis, Monsol its ratio of germicidal power gonorrhoea. known antiseptic of its class, an

D STAFFORD

CRYSTALLINE VITAMIN D
(Calciferol)

Following the recent publication of an announcement that British scientists have succeeded in isolating Vitamin D in a crystalline form (*Nature*, 1931, Vol. 128, p. 758), The British Drug Houses have undertaken the manufacture of this pure crystalline Vitamin D (named Calciferol), and now offer it for the use of research workers.

Calciferol is a white substance of definite crystalline structure and of absolute purity; it possesses an unvarying Vitamin D activity of 40,000 units per mg.

Calciferol is issued in tubes of 0.1 gram which are obtainable from the makers at 12/- each.

Calco

ALOCOL

Colloidal Hydroxide of Aluminium

THE increasing prevalence of gastric ulcer and hyperchlorhydria has produced an advance in the treatment of these diseases.

"Alocol" (Colloidal Hydroxide of Aluminium) provides an antacid medicament far superior to subnitrate of bismuth, bicarbonate of soda and other alkalis. These merely afford a certain degree of ease, without bringing about a permanent relief of the condition.

"Alocol" absorbs the excess of hydrochloric acid without interfering with the normal antiputrefactive function of the gastric juice or harmfully affecting the processes of nutrition.

"Alocol" has been subject to extensive clinical trial, and literature giving full particulars of the results will be gladly sent to medical men on request.

A Distinct Advance Over Preparations of Acetyl-Salicylic Acid

Acetyl-salicylic acid possesses a notable disadvantage. Physicians have proved that it cannot be tolerated by patients suffering with a delicate stomach. Consequently, the value of this medicament in the wide field in which it is indicated is very seriously reduced.

"Alasil" completely overcomes this objection. By combining calcium acetyl-salicylate with "Alocol," unfavourable secondary action upon the stomach is prevented. This beneficial influence is undoubtedly due to the presence of "Alocol" (Colloidol Hydroxide of Aluminium), which preparation has brilliantly stood the test of practice in the treatment of hyperacidity and other ill conditions of the gastric tract. "Alasil" is therefore a triumph over acetyl-salicylic acid. It enables higher doses to be administered and maintains the patient's system under its influence for a greater length of time. Analgesic, Antipyretic, and Sedative. "Alasil" is indicated in all cases where acetyl-salicylic acid has been used heretofore.

A supply for clinical trial with full descriptive literature sent free on request.

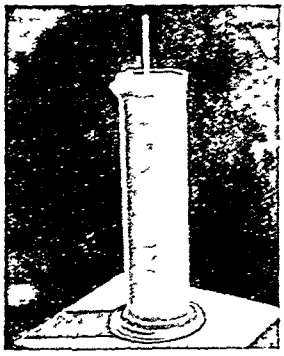
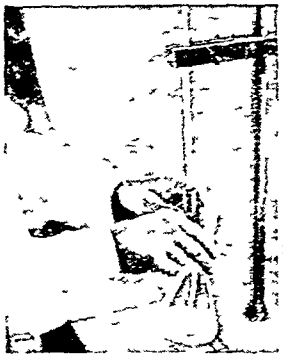
STANDARDIZATION OF THE INGREDIENTS OF THIS FAMOUS BRITISH PRODUCT



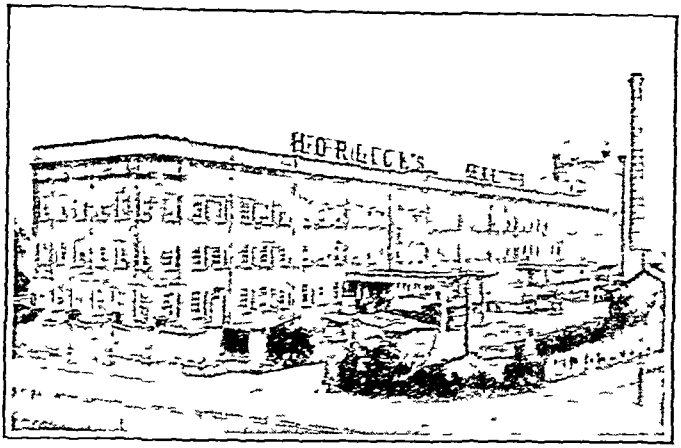
A certificate of milk testing done in the laboratory at Slough. Every churn of milk is tested for purity and richness before it leaves the producer and is even tested more strictly than ever by the Horlick experts. Three of these tests as shown here are carried out at once but 3 or 4 times later on arrival

★



Determining the amount of cream in the milk. The fat content of milk used in Horlick's Malted Milk is always decidedly above Government standards

★



A lactometer floating in a sample of milk registers the specific gravity from which can be calculated the amount of solids present

★

Testing for acidity. A standard quantity of milk is put in a glass vessel and neutralized with a standard chemical solution. This indicates the freshness of the meal and its suitability for use. If milk is too acid it cannot be heated or used for Horlick's

With Horlick's you can be sure you are prescribing an "ALL BRITISH" PRODUCT

HORLICK'S was originated half a century ago by an Englishman, Sir James Horlick, Bart., and year by year it has won ever-increasing popularity, until to-day it is confidently recommended by the medical profession all over the world.

Just now, when patriotic men and women are uniting their efforts to support home industries, it is particularly satisfactory for doctors and nurses to know that Horlick's Malted Milk is an "all British" product.

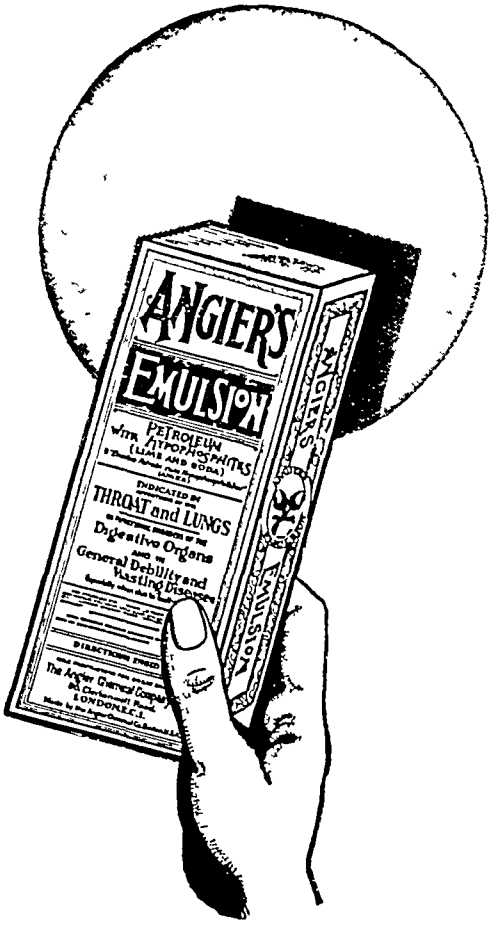
ENGLISH DAIRY FARMS SUPPLY THE FRESH FULL-CREAM MILK THAT GOES INTO HORLICK'S

Cows fed on the richest pasture lands of England produce the fresh full-cream milk from which Horlick's is made. Barley from the eastern counties—malted at Horlick's own Maltings in Norfolk—and home-milled British wheat only are used in its manufacture.

BRITISH EMPLOYEES

Horlick's Malted Milk Company, Ltd., is wholly English in Directorate and capital. From factory hand to skilled technician in the Laboratories and Test Rooms—**right through the organization British labour is employed.**

EVEN THE BOTTLES ARE BRITISH!



Only British material is used in Horlick's factory, even the bottles in which Horlick's is packed and the paper in which it is wrapped are **made in England.**

Horlick's Malted Milk Company, Ltd., Slough, Bucks.

Bronchitis, Winter Cough,

Influenza and Sequelae.

There is a vast amount of evidence of the most positive character proving the efficacy of Angier's Emulsion in sub-acute and chronic bronchitis. It not only relieves the cough, facilitates expectoration, and allays inflammation, but it likewise improves nutrition and effectually overcomes the constitutional debility so frequently associated with these cases. Bronchial patients are nearly always pleased with Angier's Emulsion, and often comment upon its soothing, "comforting" effects.

The unique soothing properties of Angier's Emulsion, its favourable influence upon assimilation and nutrition, and its general tonic effects, make it eminently useful both during and after influenza. It has a well-established reputation for efficiency in relieving the troublesome laryngeal or tracheal cough, correcting the gastro-intestinal symptoms and combating the nervous depression and debility.

Collosol "F.C.V.D."

FOR BLOOD REGENERATION, RECTIFYING CALCIUM DEFICIENCY AND GROWTH PROMOTION

Facsimile of label

In recent years the work of Hart, Steenbock, McHargue, Elvehjem, and others, suggests that the beneficial effect of iron therapy is largely due to the presence of a minute copper content present as an impurity.

Collosol "F.C.V.D." comprises colloidal iron activated by a small quantity of copper. Further, as calcium deficiency is frequently associated with anaemias and debility it has been considered advisable to make use of the well-established function of Vitamin D in calcium absorption. This accessory food factor has been added in the form of irradiated ergosterol combined in the medium of pure malt extract (Vitamin B) with orange juice (Vitamin C).

Other preparations of activated iron are issued as follows:—

Collosol Ferrum et Cuprum	Cuprum 1 part in 20,000	Injection 1 and 2 c.c.s Rubber Capped Bottles 30 c.c.	Oral 4 ozs. 8, 16, 80
Collosol Ferro Arsenic et Cuprum			
Collosol Ferro Manganese et Cuprum

BETTER MILK FOR BABIES

ORDINARY MILK

1/1,000 c.c. plated—over 200,000 bacteria per c.c.

LACTOGEN
Full strength mixture.

1/10 c.c. plated—less than 100 bacteria per c.c.

FACTS ABOUT LACTOGEN

Purity

Lactogen is under hygienic and scientific control from the time the raw milk is collected until the despatch of the finished product.

The fresh milk used for its preparation is obtained from selected farms, the herds receiving constant supervision from the Company's farm inspector.

A stringent examination is also carried out in the laboratory, and with these precautions a constant degree of purity is maintained.

The modern manufacturing process is carried out under the most strictly hygienic conditions, and the bacterial count of Lactogen, as reconstituted, is less than 100 organisms per c.c.

Lactogen is prepared in England by Nestlé's—famous for more than fifty years for the purity of their milk products—from the pure, fresh milk of specially selected herds, grazing on picked English farms.

Lactogen is neither a new nor untried product. First introduced in Australia, it has for many years enjoyed a large sale in overseas countries.

FREE SAMPLES with detailed descriptive literature will be sent to any Member of the Medical Profession upon request.

BETTER MILK FOR BABIES

A natural
COD LIVER OIL CONCENTRATE
containing both vitamins
A *and* D
in a pleasant tablet form

The Vitamins A and D in their intimate natural association are the essential and vital principles of Pure Cod Liver Oil. The fats in the oil are of relatively small importance and are, in fact, disadvantageous in the numerous cases of fat intolerance.

White's Cod Liver Oil Concentrate represents 100% of therapeutic efficiency. Each tablet contains not less than 500 vitamin A units when essayed for xerophthalmia and 200 vitamin D units when essayed for rickets by the McCollum Line Test; equal to a teaspoonful of a high-grade Cod Liver Oil.

White's Cod Liver Oil Concentrate is a *natural and not a synthetic product*—a matter of the greatest therapeutical and clinical importance. The potency and stability of each tablet is guaranteed. Its small bulk (only 1½ of the oil), great palatability and very ready digestibility are appreciated by patients of all ages.

Indications—Tuberculosis. Rickets. Anæmia. Malnutrition. Infantile Weakness. Deficiency Diseases. Nervous Diseases. Wasting Diseases. Respiratory Diseases. Adult Weakness.

And, wherever COD-LIVER OIL is indicated.

Unlike emulsions, these tablets contain no gum or objectionable flavouring matter, and they cause no nausea or irritability. White's Concentrate of Cod-Liver Oil Tablets are extremely palatable, and being of small size, they are very easily administered, for instance, one tablet is fully equal to the B.P. dose of Cod-Liver Oil for a child.

Every physician interested in Cod-Liver Oil Medication is invited to send for a full Clinical Sample free of charge.

The BULB

Shewing Apparatus attached to ordinary rubber tubing.

AN ESSENTIAL INCLUSION IN THE MIDWIFERY BAG

CO_2 IN RESUSCITATION.

"F. B. R." in the "British Medical Journal," Nov. 7th, 1931, page 878, writes:—

"Apropos CO_2 as a respiratory stimulant, at a recent confinement, as the result of premedication of the mother, of instrumental delivery, or of some cause unknown, the child was born in a condition of partial asphyxia. Half an hour's effort to restore respiration proved ineffective, beyond producing a spasmodic inspiratory gasp at intervals. The baby appeared to have definitely decided not to remain. It then occurred to me to try the "Sparklet" apparatus, or, I should rather say, contrivance, which one carries in the anaesthetic bag. The result of discharging a little CO_2 in front of the baby's mouth at the moment of its making a rare inspiratory effort was instant and amazingly effective. The rhythm was started, and in a few minutes all anxiety had vanished. Admittedly there is nothing startlingly new in this phenomenon. I feel, however, that I am justified in relating the experience from the conviction that the average practitioner is unaware that he has to his hand a simple inexpensive little CO_2 container, suggested by a Manchester anaesthetist and manufactured by the "Sparklet" people. I now feel it should have a place in every midwifery bag, and that it will save many an infant life."

PRICES.

APPARATUS complete 32/6
6 "J-size" Bulbs - - 10/6
Refilling EMPTY Bulbs, each 9d.

The Apparatus consists of a Fine Adjustment Valve fitted with an attachment for holding a Sparklet "J-size" Bulb containing Carbon Dioxide. The Valve provides a delicate means of regulating the flow of gas, and each Bulb contains sufficient CO_2 to deliver for 6 minutes at rate of 2 litres per minute.

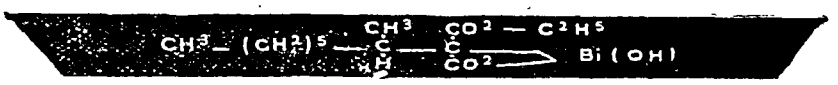
PART OF PAGE OF THE *HISTORIA ECCLESIASTICA* COMPILED BY THE VENERABLE BEDE "THE FATHER OF ENGLISH HISTORY."

Bede is the pioneer historian of Saxon England. His "Ecclesiastical History" (he does not confine himself purely to ecclesiastical matters) is our most valuable document for the period about which he writes. Its simple and unaffected style, its beauty of spirit and the apparent strong desire of its author to gather the true facts make it one of the most valuable and attractive historical works ever written. Bede's history and other writings, which included works in grammar, astronomy, chronology and the calendar, a book of songs (some of them of his own composition), a book of epigrams, a book of the "Art of Poetry" and of the "Nature of Things" and a book of Orthography, exercised an unparalleled influence abroad as well as in England over the learning of mediæval Europe; he was the "Master of the Middle Ages." His last work was the translation into the vernacular of St. John's Gospel, the text of which has been lost.



Date: of Bede's life, A.D. 672-735
of the manuscript, A.D. 800

2 lbs. of BRITISH milk
in 1-lb. of Cadbury's Milk Chocolate

How much milk is there in one pound of Cadbury's Milk Chocolate? The answer is: *Two* pounds! In one pound of chocolate there are two pounds of milk and three-quarters of a pound of chocolate containing the purest crystalline sugar. The explanation is that Cadbury's process drives off 87% of water from the two pounds of milk, so that the concentrated milk left has eight times the food value, weight for weight, of the original milk.

William Mitchell Banks Lecture

ON

THE PROBLEM OF THE STIFF JOINT

DELIVERED AT THE LIVERPOOL MEDICAL INSTITUTION
NOVEMBER 19TH, 1931

BY

SIR ROBERT JONES, BT., K.B.E., C.B., F.R.C.S.

As an old pupil of Sir William Mitchell Banks I have a vivid recollection of his strong and charming personality and of his influence over his colleagues, not only in this city, but throughout the country. He was, without exception, the most interesting and lucid lecturer to whom I have ever listened, and his anatomical demonstrations, enriched by aphorism and an eloquence peculiarly his own, fascinated all who were privileged to attend his classes. His eminence as a surgeon will always be recognized; his contributions to the literature of his art are many and enduring. Medical education was a subject dear to his heart, and we in Liverpool will remember gratefully the important part he played in laying the foundations of our University. Our profession is enriched by the example he set in maintaining its noblest traditions.

In one of the last letters I received from Sir William he deplored the fact that the bone-setters were making inroads on the reputation of our profession, and he asked, "When shall we wake up?" This has influenced me in choosing for the title of my address "The problem of the stiff joint." It is a subject which is of interest to surgeons generally, and has a far-reaching importance to every practitioner of medicine. The field it covers is so extensive that in the brief time at my disposal I can only touch lightly upon points which seem essential and fundamental. The ordinary textbook, if it deals with the question at all, does so in an indefinite way, and invariably leaves us without practical guidance; as a sequel to this we have unqualified practitioners all over the country who render stiff joints mobile with a success sometimes very disconcerting. Later on I shall deal in some detail with so-called "bone-setting" or "manipulative surgery," and formulate rules which may guide us in our endeavour to prevent a joint from becoming stiff, and, if stiffness has occurred, try to indicate whether rest or movement is needed. This will entail a repetition of principles which I have taught for many years, and perhaps I may be excused if my address seems elementary, as my object is to be helpful to all practitioners interested in the problem.

When a joint is stiff it is generally due to the presence of adhesions, which may be found within a joint or around it. Very often they are both extra- and intra-articular. They may be the sole cause of the stiffness, or complicate disease.

WHAT IS AN ADHESION?

An adhesion is a pathological band restricting the normal movement between two adjacent tissues, and it is caused by a serous or haemorrhagic exudate from the blood vessels, either inflammatory or traumatic in origin. At first this exudate is soft and elastic; later, as its structure becomes more definitely fibrous, it loses its elasticity and becomes more dense and less vascular. An adhesion in its latest stage, therefore, is a cicatrix. If an inflamed joint be kept at rest too long after inflammation has abated then the process of healing may lead to the formation of unnecessary bands of fibrous tissue.

To simplify discussion adhesions may be divided into two groups: (*a*) the extra-articular; (*b*) the intra-articular.

The extra-articular type may be connected with the capsule, with the ligaments, or with muscular origins and insertions. They may be due to old organized blood clot and plastic effusion following tears in muscle. They may form between muscles and their sheaths, or be due to the irritation of displaced tendons, or the slipping of muscles or muscular fibres over bony prominences, as so often occurs about the spine. Although stiffness in joints is usually the direct result of adhesions, mobility of a joint may sometimes be interfered with by adaptive shortening of muscles, and other structures due to posture, or strain, or loss of substance. It is met with in myositis ossificans, Volkmann's ischaemic paralysis, and in the form of sclerosing fibrositis, such as we find in Dupuytren's contraction. It is found in an intractable form in many deep scars about joints.

Intra-articular stiffness may be the result of a simple trauma with or without infection. In its simplest form it may consist of an adhesive fixation between adjacent portions of the synovial membrane or capsule. It often follows injuries to the semilunar cartilages, the infrapatellar pad, dislocations, fractures into the joint, or it may result from acute or chronic infection. For purposes of this address I will use the term arthritis as denoting an inflammation involving the cartilage or bone, or both, as distinct from a simple synovitis. It is an artificial distinction, but will simplify the problem with which I deal.

REST OR MOVEMENT

We may lay down as a rule of practice, admitting of few exceptions, that a joint stiffened by simple adhesions, whether intra- or extra-articular, should be moved actively or passively, or even forcibly if necessary. In contradistinction to this, with exceptions which will be stated, a joint stiffened by arthritis should be kept at rest until pain and inflammation have subsided, when movements of a special kind may be allowed. It is essential, therefore, to make a differential diagnosis between the two conditions which will provide a safe and practical guide to treatment.

The rule is a simple one and allows of few exceptions. A joint whose movement is limited in *all* directions is, or has been, subject to arthritis, while a joint which is limited in certain directions *only*, movement being normal in others, is not arthritic. This is more obvious in joints which can be moved in many directions, such as the wrist, hip, shoulder, and spine, than in the knee and elbow, where movement is mainly one of flexion and extension; but, as I will demonstrate, it applies to these also.

This differentiation does not apply to septic infections involving the tissues outside the joint nor to fractures within the joint, nor to joints temporarily stiffened from long fixation.

We can, however, definitely assume that a joint whose movement is not limited in every direction is free from arthritis. Furthermore, if we cannot find any limitation of movement in a joint we may assume it is free from both arthritis and adhesions, but the examination must be very methodical, for adhesions may exist without obvious stiffness, as I will explain when dealing with movements of the knee. In early arthritis rigidity is due to protective muscular action, which disappears under an anaesthetic. Later, this physiological rigidity will become pathological.

I will state a concrete example in order to make my meaning more clear in regard to differential diagnosis, and the spine will afford a good instance. A patient complains of pain in his back and he is asked to flex, extend, rotate, and laterally move his spine throughout its full range. If he can do this freely both arthritis and limiting adhesions can be excluded. If his spine is tender, but he cannot flex it fully or deviate it laterally, yet can, however, hyperextend it normally, we may assume the absence of arthritis. We may affirm, therefore, that a spine with movements limited in all directions is arthritic,

and, further, if one or more of its movements are normal in range we can exclude the presence of arthritis. These facts definitely simplify the solution of our problem as it affects the question of rest or movement.

It will help us still further if we assume that rigidity closely following upon trauma is generally due to adhesions which sometimes form with great rapidity. The stiffness following synovitis, acute or chronic, is due to adhesions formed between different portions of the inflamed synovial membrane. When it accompanies an arthritis it is a slow and continuous process, and is due to bands binding all the tissues entering into the formation of the joint.

Definite localized pain is experienced when adhesions are put on strain, and the tenderness can generally be localized on pressure. It is more diffuse in arthritis. An adhesion is most painful when a joint is moved, and less so when the joint surfaces are pressed together. In arthritis, pain is more pronounced when pressure is brought to bear on the bone surfaces. The temperature of the arthritic joint is usually increased over the whole articulation, while adhesions may produce localized surface temperature, but generally there is none. In arthritis the stiffness is progressive ; in adhesions it is stationary or retrogressive. In arthritis, wasting of the limb is in excess of that due to desuetude—a symptom which does not apply to stiffness due to adhesions. It should be unnecessary to suggest that radiography should be used in all cases of disease and injuries of the joints. None of us, no matter how experienced, can afford to neglect the information to be obtained in this way.

In many types of arthritis we hope to obtain a varying amount of movement after the inflammatory symptoms have subsided. In adult tuberculosis a bony ankylosis—although it only happens exceptionally—gives us least anxiety as to the future. This is especially so in weight-bearing joints, such as the ankle, knee, and hip, which are liable to break down on strain, even after many years of apparent recovery. Tuberculosis in the adult presents a serious problem, for, at the end of treatment, which may last many years, with danger of a dissemination of the bacillus, a bony ankylosis rarely occurs ; but it is a bony ankylosis we want. For these reasons in the present stage of our knowledge an ankylosing operation on the ankle, knee, or hip is justifiable as soon as an accurate diagnosis has been made. It saves time in an adult patient, lessens danger, and secures a firm joint for all time. This, of course, does not apply to children. Movement is anathema to a tuberculous joint during the progress of disease, and we should make ourselves familiar with its clinical manifestations in its early stages, for here radiography may not be convincing. A skin test, though helpful in a doubtful case, is more reliable when negative than positive, while the bacillus is often difficult to find in fluid aspirated from the joint. In spite of our clinical experience there will remain exceptional cases where a diagnosis must ultimately depend upon histological findings or upon animal inoculation.

PREVENTION OF STIFFNESS

In treating joints we aim at obtaining the best functional results, and we should therefore combat all the elements which make for stiffness, the chief of which is adhesions. It is necessary to rest an arthritic joint until pain and inflammation have disappeared. In certain cases of chronic arthritis it is sometimes possible to prevent the formation of firm adhesions. This should only be attempted when the painful active stage is passed. The patient may be allowed to move his joint within a painless area, or even the surgeon may employ a passive movement once a day and then let the joint rest. It is only justifiable to proceed with this when neither persistent pain nor reaction occurs. In the non-arthritic joint, movement is needed before the adhesions have formed, or, failing that, before they have become firm. We must bear in mind that the presence of firm adhesions generally denotes some defect in treatment, and may be used against us as a reproach. Manipulative surgery would be but rarely invoked if we all made a practice of strangling an adhesion at its birth.

When we examine an injured joint we must endeavour to make a precise diagnosis and to appreciate its pathology. If ligaments are torn they should be protected from strain until movements can safely be practised. Massage immediately after the injury, before effusion has taken place, checks haemorrhage into the part, stops effusion of lymph, relieves pain, and leaves the tissues ready to commence immediate union. Massage does not include movement. A masseur who will not massage without moving a joint often disturbs tissues which should be left at rest to undergo repairs. If we understand the anatomy and function of an injured ligament certain movements of the joint can be conducted without straining it ; the joint should not be dealt with as if an active inflammation existed, for movement carefully supervised expedites the restoration of function. Local effusion of blood should be lessened by pressure, for pain is due to mechanical tension, and tension to serous and haemorrhagic exudate, and this exudate is the basis for the development of adhesions. If the joint is sprained, elastic pressure should be firmly applied in order to prevent or minimize effusion and allow of the repair of the injured structures. In the knee, for instance, if the internal lateral ligament is strained, pressure should be applied by pad and bandage, which prevents effusion about the torn ligament and distension of the joint, which so often accompanies this injury. In this early stage no movement should be allowed which gives rise to pain, and, later, when movement is allowed, care should be taken to prevent strain upon the injured ligament. Neglect of this rule is often the cause of lateral yielding of the joint, for the torn ligament, although united, may lengthen under strain. In the lower extremity active movements should be practised in the first place without the incidence of body weight, and when walking is prescribed body weight should be deflected from the injured ligament. For instance, by raising the heel of the boot on the inner border, the internal lateral ligament of the knee and of the ankle are relieved from strain. The same principles apply to strains of tendons, as exemplified in partial or complete rupture of the tendo Achillis, where we first keep the ankle in plantar flexion until healing takes place, and then add to the height of the heel to avoid strain during walking. These rules will prove a useful guide, and, although obvious and elementary, they seem constantly to be neglected.

STIFFNESS FOLLOWING FRACTURES IN AND ABOUT JOINTS

I have often stated that prolonged rest of a healthy joint within the limits of its normal range of movement will not give rise to more than a temporary stiffness, easily overcome by passive movements in the case of the adolescent and the young adult. In the aged this stiffness is more pronounced. Against this it may be urged that a very intractable stiffness sometimes follows fractures of the femur near the knee when this joint has been kept extended for a considerable time. This is perfectly true, but other factors than rest are involved. In such cases considerable (and, at the time, unrecognized) injury may have occurred to the joint, and be responsible for the development of adhesions. In addition to this, reaction

occurs from the stretching of capsule and ligaments. Both these complications must be avoided without imperilling union of the fractured ends. The problem must be worked out in each individual case. When fracture occurs in middle life and in the aged, where there has probably been damage to the joint structures, the joint should be slightly flexed from time to time, and should never be fixed in the fully extended—which so often becomes the hyperextended—position. A joint *stiffens* much more readily if it is rested in the fully extended, rather than in the slightly flexed, position. This is true of all joints, but more especially of the knee, elbow, and fingers. We found this emphasized during the great war, where fractures of the humerus were treated by extension of the elbow, and injuries of the wrist were fixed in dorsiflexion splints with straight handpiece, which involved full extension of the fingers. Where the handpiece was curved, allowing of slight flexion of the joints, these stiff fingers were rarely encountered. Fractures into the elbow-, knee-, and ankle-joints usually unite sufficiently in three or four weeks to permit of gentle passive movements. The stiff joints following compound fractures of the bones come within a different class, and will be referred to later. To avoid adhesions, therefore, we should allay all inflammatory symptoms; prevent or lessen local effusion by pressure; massage injured structures early; practise movements which place no strain on the injured tissues, and so encourage early active function.

TREATMENT OF STIFFNESS DUE TO ARTHRITIS

Radiology is obviously of paramount importance in helping us to decide whether a joint should be moved or not. It has a definite message in tuberculosis of bone, and in every variety of non-tuberculous disease it will help us. If we find extensive destruction of bone and disappearance of cartilage, as shown by diminution of joint space, manipulation will not be indicated, and in those cases of minor changes we must approach the problem of movement with great caution. Movement has no part in the treatment of arthritis during the painful inflammatory stage. It has but a limited scope where recovery from active disease has occurred. It is not easy to fix the moment when disease is no longer active in an arthritic joint, but the absence of pain and radiological evidence of repair are welcome signs.

We may be sure that a joint has recovered from disease when its range of movement is not diminished by use, or, in the case of an ankylosis, when its position does not alter by use. If a joint has a range of movement of 40 degrees, and this range is diminished by 20 or 30 degrees when use has been allowed, we can be sure that disease is still active. Or supposing a joint is fixed at a certain angle by fibrous ankylosis, and, when used, it becomes *fixed* at another angle, we know that recovery has not taken place, and that manipulation would be disastrous. Or, again, if after use it remains at the same angle, we look upon the joint as recovered, with what Thomas termed a fixed, sound ankylosis. Should the patient return with an increasing range of movement we may consider the joint free from active disease. A recognition of these signs of recovery has a close relationship to treatment. When the joint seems to be quiescent, free from pain, with normal temperature, and weight-bearing produces no reaction, while the *x*-ray shows evidence of repair, these tests of recovery should be applied, and, if satisfactory, the question may arise whether surgical assistance is needed to increase the range of movement. If recovery has taken place and the range of movement increases, be it ever so slowly, we should trust to active rather than to passive movements, and these should be practised in the absence of weight-bearing. If the increase in the range of movement ceases and then remains stationary for a period the question of passive assistance may arise, but forcible manipulation is not to be considered. In the lower extremity, if the range of flexion increases when walking is permitted, while extension becomes more limited, the joint requires further protection. In the case of recovered non-tuberculous arthritis we may decide to try to increase the range of movement. We are helped in our decision by the *x*-ray photograph and by the appearance of the joint. If it has stood the strain of exercise without reaction we may increase the range of movement 10 or 20 degrees, and fix it at the new angle for twenty-four or forty-eight hours to avoid reaction; the joint can then be exercised at first without, and later with, the incidence of body weight. If the increased range is maintained the same procedure is repeated. If, on the contrary, reaction occurs and the range of movement is not maintained, or perhaps lessened, passive movements must not be permitted.

PROLONGED IMMOBILIZATION OF A FRACTURED LIMB

As I have already stated, immobilization in an adolescent or young adult need give no anxiety. After six or eight weeks the knee will recover free movement, even though there has been a sufficient pull upon it to maintain full alignment of the fracture. We have rarely experienced any trouble. After a compound suppurating fracture, where one meets with a mild peri-articular infection, or where the joint has been badly strained or forced into hyperextension, the stiffness may be pronounced and very resistant. These conditions should be dealt with by manipulation in stages, and the joint should be fixed for a few days in each new position. Lest the fracture is not firmly consolidated it must be protected from strain during manipulation by the firm application of splints. In the case of the femur the patient should be placed upon his face with his thigh splinted, and the assistant should put firm pressure over the fracture while the knee is flexed.

We are often confronted with an old mal-union or non-union of the femur and a stiff knee-joint. We should always endeavour to secure movement in the knee before operating upon the bone. If the rigidity is allowed to remain during the months necessary to treat the fracture the stiffness of the joint becomes more and more intractable. Before manipulating the knee we must make sure that the patella is mobile and that the quadriceps is not fixed to the femur, otherwise the quadriceps may be ruptured, the patella broken, or the tubercle of the tibia evulsed. It may be necessary to free these structures by open operation.

ACTIVE AND PASSIVE MOVEMENTS

And now a word about active and passive movements, for by this branch of physiotherapy we prevent the formation of adhesions and cure the less resistant types. When a joint has been sprained, and the preliminary treatment (which I have already described) has ended, the question of movement arises. If adhesions have formed movement is indicated, and active movements are to be preferred to passive ones. Active movements, being voluntary, are sure to be gentle, being limited by pain, while the muscle is truly exercised. Passive movements, unless very skilfully performed, are apt to add to cicatricial tissue and interfere with repair. In young children and highly nervous people it may be necessary to prescribe passive movements, but if you have a choice, trust to the active type. When a joint has recovered from a fracture, or mild arthritis, the masseur should be warned not to employ what I have termed the "pump handle" method when passive movements are prescribed. It consists in

putting the joint through each of its movements several times instead of once. This often produces a reaction which will stiffen, not mobilize, a joint. It most often occurs in the elbow, which becomes stiff and painful, and often alarms the practitioner. We first exclude the presence of myositis ossificans, and then assume that the symptoms are the result of excessive movements. They disappear when the joint is rested for a few days, and then active movements may be allowed. It cannot be repeated too often that if passive movement is adopted it should be confined to one single movement in each direction once a day, and in the interval the arm should be slung at right angles. No adhesions can occur in twenty-four hours which cannot easily be overcome.

MYOSITIS OSSIFICANS TRAUMATICA

For a moment we will deal with a serious complication, known as traumatic myositis ossificans. It may occur after any dislocation or fracture in the neighbourhood of a joint, but is most commonly found in the region of the elbow. It requires very careful handling. Its onset is gradual and usually painless, and when established may result in a locking of the joint. It is due to tearing of the muscular and periosteal tissue from bone, accompanied by haemorrhage. Fragments of periosteum and osteogenetic tissue are pulled away, and thus the formation of new bone takes place along the interfibrillary and intermuscular septa. The symptoms are insidious. An elbow which is doing well begins to get stiff in the third or fourth week. The practitioner, omitting to take an *x*-ray photograph, prescribes passive movements—a very dangerous thing to do. The *x*-ray would have shown a cloudiness about the attachment of some muscle—usually the brachialis anticus. In two or three weeks this shadow becomes more dense, and traces of bone structure are present. The elbow in such case should be kept quite still until evidence is obtained that bone deposit has ended. If the elbow has been slung at an acute angle it should be altered and placed in the most useful functional position, lest extra-articular ankylosis occur. When we are sure that no further bone deposit will take place—a fact easily ascertained by successive *x* rays—very gentle movements may be allowed. The deposit may be slowly absorbed or it may remain quiescent. If it causes disability it may be removed, but if it does not materially affect movement it should not be interfered with ; during its developmental stage an operation often results in fresh deposit of bone. These deposits may remain for many months, and ultimately be absorbed, or they may develop all round the joint, producing a permanent ankylosis. I emphasize this in order to restrain you from employing either massage or movements in this condition.

ISCHAEMIC PALSY

Another and more alarming complication in fractures about the elbow is known as Volkmann's ischaemic paralysis. It often produces ankylosis of the elbow-joint, with paralysis and rigidity of the fingers. The condition is due to acute venous obstruction. It may be due to pressure from within, such as haemorrhage into the antecubital fossa, pressure from displaced fragments, or pressure from without due to tight bandaging.

Symptoms usually begin in the space of a few hours after injury ; the hand is painful, the fingers discoloured and numb, and voluntary movements may be lost. Irreparable mischief may take place in forty-eight hours. Treatment should be immediate ; every minute is important. The arm should be released from all restraint likely to produce obstruction. If this is not effective valuable time must not be wasted, and the blood clot should be evacuated by an incision into the ante-cubital space. This prompt action, based as it is on a sound pathological basis, may save a calamity. I have no time to discuss the mechanical treatment of the stiff fingers, but I must warn you when dealing with fractures and dislocations about the elbow, never to flex the elbow-joint fully without first completely reducing the displaced bones. It is a highly dangerous proceeding.

FORCIBLE MANIPULATIONS

I shall now deal in some detail with the subject of forcible manipulation, which is a branch of surgery that from time immemorial has been neglected by our profession, and as a direct consequence much of it has fallen into the hands of the unqualified practitioner. Let there be no mistake ; this has seriously undermined the public confidence, which has on occasions amounted to open hostility. If we honestly face the facts this attitude should cause us no surprise. No excuse will avail us when a stiff joint, which has been treated for many months by various surgeons and practitioners without effect, rapidly regains its mobility and function at the hands of an irregular practitioner. We should be self-critical, and ask why we missed such an opportunity ourselves. The problem is not solved by pointing out mistakes made by the unqualified—the question at issue is their success. Reputations are not made in any walk of life simply by failures. Failures are common to us all, and it is a far wiser and more dignified attitude on our part to improve our armamentarium than dwell upon the mistakes made by others. With few exceptions a stiff joint is based on a clearly defined pathological basis, and a large proportion of cases cured by the manipulator represent a failure on the part of our profession. It is not a pleasant thought, but it is true. We are apt to shrug our shoulders and show contempt when a patient is told that "a vertebra is out ; I will replace it." Such a dramatic statement may have a psychological effect, and be an excellent preparation for treatment, because it inspires hope and compels confidence. Every practitioner knows the value of such a stimulus if he is to control the nervous element so often associated with an organic lesion. In the neuro-mimetic and the neuro-organic it is an essential part of treatment. The success of the manipulator has given rise to a widespread belief that he has been born with a "gift" or "intuition." Of this we have no evidence. It is obvious there is nothing which he does that should not be undertaken more safely by any surgeon or practitioner who possesses a knowledge of the anatomy and pathology of the joints, but—and this is fundamental—he must become familiar with methods of manipulation which are safe and thorough ; he must learn the art, and he must know the right joint to tackle—a mistake on his part is far less excusable than when made by the unqualified. It is often stated of H. O. Thomas that he had an unreasonable objection to moving joints, and that the breaking down of adhesions was anathema to him. His experience of bone-setters was based on their procedure over forty years ago, when not a week passed but he came in contact with tuberculous joints which had been forcibly moved, sometimes with tragic consequence. Radiography was unknown then, and joints were broken down indiscriminately ; in these days an *x*-ray photograph is in the hands of everybody, and *such calamities are proportionately few.*

I have endeavoured to indicate the type of joint which should be moved, and the stage at which this should be done, drawing attention to certain doubtful conditions which should be approached tentatively and even experimentally, and I have laid down rules which should guide us in deciding whether a joint has recovered from an arthritis or not. In rupturing non-arthritic adhesions there are certain points I wish to emphasize. Recent adhesions may be broken down under gas and oxygen

When they are of firm character full anæsthesia is essential, for complete muscular relaxation must be secured before manipulation can be thoroughly performed; they cannot be dealt with satisfactorily if there is the least muscular resistance. An advantage of the lighter anæsthesia is that the patient can be made to move his joint immediately consciousness returns, and this has an excellent moral effect. We should be familiar with the range of movements in the various joints if we are to avoid strain. The range may differ in individuals, and the sound practice is to take the healthy joint as a guide, comparing its movements during the operation with those on the affected side. After the joint has been conducted through its complete range of movement we should be satisfied, it is unnecessary to repeat it.

When adhesions are broken down the manipulation should be completed on one occasion, unless they are exceedingly firm, and the limb should be placed in the position of full correction while the patient is unconscious. If, for instance, the shoulder has been fixed in adduction he should be allowed to awake with the arm in full abduction. If, on the other hand, the manipulation has been very severe, and reaction is feared, the joint should be rested for a day or two, massage being employed instead of movements.

I have emphasized the necessity of putting the joint through its complete range of movements, and to make this clear I will briefly describe the technique which I follow on the three joints most generally associated with adhesions—the knee, shoulder, and elbow.

Technique in Manipulating the Knee

In breaking down adhesions the joint should be fully flexed, and in that position the leg is rotated out and in. This rotation should be continued while the knee is being fully extended, care being taken that the extension is complete. The knee is again flexed over the surgeon's forearm, which is placed across the popliteal space—in this way the tibia is levered slightly forward. If the adhesions are in front of the joint the knee should be flexed while the hip joint is hyperextended, in order that extra tension may be put upon the structures in front of the joint. This is a most important movement and is often neglected.

If, after injury, a patient is unable to extend his knee fully, we may suspect an unreduced semilunar cartilage, sometimes but far more rarely, a fracture or evulsion of the tibial spine clearly seen on an *x*-ray film. A displaced semilunar cartilage may be reduced by manipulation even after several months. The knee should be flexed and rotated inwards then abducted during extension in the case of the *internal* cartilage, in dealing with the *external* cartilage the tibia should be rotated outwards and adducted. In addition, the manipulation which I have described for breaking down adhesions should be practised, for adhesions are often found in connexion with a displaced cartilage. Unless the knee extends fully and easily we may be sure the meniscus is not reduced.

The Shoulder

The shoulder-joint is very commonly bound down by adhesions even after very slight injury. It is apt to occur in the aged, more especially following fractures and dislocations. All fractures about the shoulder where adhesions may be expected should be treated in the abducted position. In the fragile and aged this position may not be tolerated, and the arm will then have to be kept against the side, and gentle passive movements started in the third week.

In breaking down shoulder adhesions, especially in the aged, great care is needed, for it is not difficult to produce a fracture or dislocation. This unpleasant occurrence is apt to be associated with rotation outwards or abduction, and the padded fist should be pushed into the axilla in support of the head and neck when manipulation is practised. In this joint it is especially necessary to check manipulation by comparing the range of movements with those of the sound side. The patient should lie on his back, with the injured shoulder protruding over the edge of the table. The arm should then be rotated inwards and outwards, and while the scapula is fixed the arm should be completely adducted and abducted. In this position it should again be rotated inwards and outwards. The scapula should next be released and allowed to move with the arm, while it is fully elevated. In this position it should again be rotated inwards so that the forearm can easily be placed behind the back, and outwards so that the arm can be placed behind the neck. The arm should then be circumducted, while being brought down to the side. Finally—and this is an important and often neglected movement—the arms are elevated and the hands placed behind the head, and from this position the arm is pushed backwards, the head of the humerus stretching the front part of the capsule. If adhesions are very firm these movements may have to be done in stages, but where possible it is best that they should be completed on one occasion.

The Elbow Joint

In breaking down adhesions about the elbow joint especial care is needed. If the arm recent and not accompanied by fracture the joint should be put through its complete range of movement. If the adhesions are very firm and are associated with a fracture, or follow a dislocation, mobility should be brought about in stages. My practice is first to extend the arm to the point of safety, which I estimate by the degree of resistance it offers, and then I flex it, using only very slight force. The arm is then slung in flexion and kept there for two or three days, when it is extended, and kept in extension for a couple of days. If no reaction has taken place the sling should be removed and active movements allowed. It may be necessary to repeat this routine in a few days. If the range of movement increases with use, no matter how slowly, neither passive nor forced movements should be allowed. We should remember that in children a stiff elbow often becomes mobile with active use when it resents passive movement, and it frequently happens that when massage and passive movements have failed to make any impression, and have been discontinued, the child appears a few months later with a freely movable joint. It is not uncommon to meet with a stiff joint in an adolescent following a fracture through the condyle which has not been accurately reduced. The elbow usually assumes an angle of about 40 degrees from full extension. This ankylosis, if roughly handled, may react and the joint become inflamed, so to avoid that we flex the elbow without using much force, until strong obstruction is met with, and then we keep it slung in its new position for a few days, after which we find it easy to obtain a further flexion of 10 or 20 degrees. This routine is repeated two or three times, and the result is often most encouraging, for we may secure a considerable range of movement at a more useful angle in a joint that otherwise would remain very stiff.

These manipulations are applied to firm peri-articular or intra-articular adhesions, not those accompanied by destruction of joint surfaces.

After-Treatment

The after-treatment of joints following forcible manipulation is important. Active movements should be started as soon as consciousness is restored. It may be necessary to assist these movements passively once a day, active movements should be repeated frequently. If effusion takes place in a joint it is strongly suggestive of the rupture of intra-articular adhesions, but such effusion does not necessarily imply that the manipulation should not have been employed unless it is followed by a progressive diminution of the range of movement. If this occurs rest is called for, the limb being fixed in a position opposed to the contraction. Recovery will be expedited by dealing with the joint persuasively rather than forcibly, but if, even in the presence of considerable pain the range of movement is increased by exercise, rest is contraindicated. Pain which is sharp and of short duration is negligible, but if pain persists when the joint is at rest it means that a reaction, likely to be followed by stiffness, has set in, and is a danger signal calling for pause. If a patient is able to move his joint freely after manipulation he is encouraged to use it freely. Exercise is better for him than any form of physiotherapy.

The stiffness following chronic arthritis, or firm peri-articular adhesions following sepsis, must be approached with considerable caution. It should be a carefully conducted experiment, for we cannot always predict whether or not a reaction will occur.

I will illustrate this by again taking the knee-joint as an example, assuming that there have been no destructive changes in the bone. If it is fixed in extension it should be moved a few degrees in flexion—the range depending on the resistance. The limb is then placed in a splint in order to retain the knee in its new position. It is rested there for a few days. The bandage is then removed, and the surgeon assists the patient to extend his knee. If this is successful the splint and the knee are still further flexed, and the joint is rested in its new position. If the range of movement is maintained we know we can continue on these lines and bring about a more complete mobilization. If it becomes fixed in its fresh position, and in spite of all coaxing remains fixed, we must face failure, and we must let the joint ankylose in the best functional position. It is well to remember that often when no amount of forcible manipulation will move the knee it may gradually yield under continuous pressure by bandage over splint.

ACUTE SUPPURATIVE SYNOVITIS

A very anxious problem is that of the acute suppurative synovitis, which, without treatment, ends in firm fibrous, or more often bony, ankylosis. Can anything be done to modify or prevent this ankylosis? If it occurs, say, in the knee, immediate evacuation of fluid content is indicated. If this is done while the content is serous or mildly sero-purulent, destruction of the joint may be obviated; it should be well washed out with saline, alcohol, or ether. This can conveniently be done by introducing two aspirating needles, one being used as an exit while lotion is driven through the other. This is repeated, if necessary, on several occasions until the discharge is serous; when this has occurred the joint should be fixed for twenty-four hours in extension, and then for the same time in about 50 degrees of flexion to prevent the formation of fixed adhesions, which, in this acute condition, form very rapidly. When the acute symptoms are over, assisted active movements without body weight should be prescribed. If, however, destructive suppuration sets in, the joint should be opened, and movements as initiated by Willems, and developed by Everidge, during the great war, are called for.

Everidge devised a very ingenious apparatus to aid the patient's will power in moving the joint. Two transverse incisions are made into the joint from the inner and outer borders of the patella along the lines of cleavage, each about one inch in length, without involving the lateral ligaments. The cut synovial membrane is stitched to the skin. I had opportunities of examining Everidge's cases during the war, and was very much impressed by what I saw. The joint was treated as if it were an empyema, and 50 per cent. of the cases ended with useful movement. The patients became interested in carrying out the exercises, and several told me that when the joint became painful they evacuated the pus by flexing and extending the joint, and thus obtained relief. By these movements, practised every two hours night and day, the retention of pus was avoided. This treatment is not so successful in suppurative arthritis involving all the elements of the joint, and of no use when osteomyelitis invades the joint from the bones without. Such cases invariably end in ankylosis.

THE RHEUMATOID GROUP OF CASES

The rheumatoid group of cases form a large proportion of the diseases we meet with in joints, and their discussion can be approached from many angles. I will confine myself, and that very briefly, to a few surgical points on their management without reference to the etiological problem they present. For this purpose the groups may be classified as "proliferative" and "degenerative."

The proliferative type, most commonly found in the young, is characteristically polyarticular, the swelling of the joints being firm, dense, and rarely fluctuant. The clinical picture is that of a resistant, long-continued, acute or subacute joint affection, very sensitive and painful, and prone to early malposition and to early ankylosis. The *x*-ray film shows a bone with a diminished line shadow, somewhat mottled and stippled. The joint space is narrowed, and lipping is not present to any extent. Bony ankylosis is frequent and the prognosis is grave.

The degenerative type is characterized by early lipping and late hyperostosis, and the prognosis is much more favourable, for the destruction of the joint is less rapid, the lesion being first confined to the synovial membrane and to the edges of the joint.

The surgical indication in either condition is preventive. We should visualize the deformities found in the neglected case, and prevent them from occurring, so that if ankylosis takes place the functional disability will be at its minimum. This is usually within the power of the surgeon, and treatment should not be delayed while etiological investigations are being made. A visit to any spa will reveal cases in every condition of life with appalling deformities which should never have happened had there been a working association between a physician and a surgeon. In either type the hips and knees should not be allowed to contract, nor the wrists to palmar-flex. With the disappearance of acute symptoms in the proliferative variety very gentle movements should be encouraged under close observation, for considerable judgement is required to estimate the proportion between rest and movement. The exercises should in the main be active rather than passive, and if persistent pain follows without increase of mobility harm is being done. Where many joints are affected it is wise to apply the test to one, and if no reaction follows, the others can be approached. By choosing the right moment and observing the behaviour of the joint we may be enabled to retain some movement, even in the proliferative type.

In the degenerative group systematic movement without an anaesthetic is called for, but we must sail cautiously between Scylla and Charybdis. Persistent pain and swelling without a gain in movement should warn us of excessive exercise. When many joints are affected and ankylosis seems inevitable we should decide in what positions the limbs should be placed to attain the most useful function. For instance, if we have two ankylosed hips and two ankylosed knees they are more useful slightly flexed at angles which will enable the patient to sit. If these joints are ankylosed in the extended position the plight of the patient is hopeless. This is especially important in elderly people, who are unfitted to bear the strain of later operative correction.

Traumatic osteo-arthritis in which there is no evidence of infection may be caused by the faulty incidence of body weight upon a joint, as so often occurs in malunited fractures, or from the irritation of an old fracture within the joint. It is often found in haemophilia from the continued presence of haemorrhage, or from trauma due to recurring displacements of the semilunar cartilage, or it may follow occupational strain. The treatment should be modified to suit each individual case.

We very commonly meet with a hypertrophic osteo-arthritis, generally monarticular, which affects elderly people. It frequently follows injury, and most frequently involves the hip-joint. Limitations in movement occur early, and disability, slight at first, slowly increases. In the later stages an *x*-ray photograph shows a diminution of joint space and progressive lipping. This condition should not be treated in its early stages by fixation of the joint, but movement should be strictly regulated. Exercises should be practised without weight bearing,

ıd should be governed by the character and duration of
ıe pain. A pain which rapidly disappears when the
oint is rested may be ignored; if, however, it persists
or a considerable time we may be certain that the move-
ents of the joint have been excessive and should be
odified. In the later stages, if the disease advances, the
g appears shortened, because of adduction and elevation
the pelvis. Pain may be very severe and surgical in-
rvention is called for. We find that adhesions are
ommonly associated with the bony changes, and often
careful manipulation under anaesthesia gives great relief
nd increases the range of movement. If the joint moves
asily under manipulation no fixation beyond a flannel
pica is needed, but if there be excessive osteophytic out-
rowths, and the joint feels resistant to manipulation,
dduction should be corrected and the joint should be
xed in plaster in the corrected position; subsequently
leather fixation corset should be worn. Operative
easures are needed in the more advanced cases, which
annot otherwise be relieved, and where the physical con-
itions are favourable.

TREATMENT OF FIXED ANKYLOSIS

Before concluding my address I will state very briefly
he principles which should guide us in the management
f fixed or permanent ankylosis. We know the malposi-
ions where joints become ankylosed if left to the unaided
fforts of nature, and I will now indicate the positions
which should be aimed at to secure the most useful
unction.

In the *shoulder* the arm should be abducted to
0 degrees, the elbow resting in front of the coronal plane
o that, when it is at right angles and the forearm supin-
ted, the palm of the hand is towards the face. The angle
at which an *elbow* is placed will depend upon the patient
nd his occupation. Most people find it more useful
when placed a few degrees below a right angle. If
ronation and supination are lost the radius should be
held midway between pronation and supination. The
wrist should be dorsiflexed at an angle of about 25
degrees. The *hip* should be ankylosed with very slight
abduction, very slight flexion—20 to 25 degrees—and
very slight external rotation. The *knee* should be placed
short of complete extension, and the *foot* at right angles
to the *leg*.

OSTEOTOMY

Osteotomy has an important place in the correction of
deformity and the restoration of correct alignment. It
should not be performed in the presence of active disease.
Its uses are mainly in connexion with deformities at the
hip or knee, and it is most effective where the ankylosis
is bony.

In the hip it is employed to correct rotation, flexion,
abduction, and adduction. The position of election is
low transtrochanteric or intertrochanteric, although it is
sometimes advisable to make the section just below the
lesser trochanter. If there is much flexion deformity the
higher section should be made, otherwise when the limb is
extended the upper end will protrude anteriorly and
jeopardize the vessels, or result in a non-union. If the
section is intertrochanteric, or through the lower part of
the great trochanter, the removal of a wedge of bone
may be necessary, especially if the neck is shortened or
the head displaced upwards. In all osteotomies of the
upper femur the adductors should be divided.

Osteotomy is frequently performed to correct adduction
in a tuberculous hip. Adduction is accompanied by
elevation of the pelvis on the diseased side, and this
results in a practical shortening of the leg. It is due to
cicatricial contraction of an unsound ankylosis at the
joint; to contraction and shortening of the adductor
muscles; to elevation of the trochanter following absorp-
tion or displacement of the head and neck; and is
increased when walking, because of faulty deflexion of
body weight. Adduction is not primarily the result of
walking, for it may occur while the patient is lying if
the joint is not efficiently controlled. The main cause is
an unsound ankylosis with absorption of bone and the
formation of strong cicatricial tissue. If the joint is not
controlled the cicatricial contraction proceeds until adduc-
tion is complete, and it is at this stage only that an
osteotomy can be performed without danger of recur-
rence. During and after adolescence an extra-articular
bony fixation may be employed, either with or without
an osteotomy. If the hip has been kept in good position
an extra-articular fixation is all that need be done. In
children, where adduction is often accompanied by move-
ment, and time is not so important a factor, an extra-
articular bony fixation is not indicated. When a bony
ankylosis of the knee is accompanied by a lateral devia-
tion, or a genu recurvatum, osteotomy is needed to
correct the deformity. This can be performed through
the femur or the tibia. If the recurvatum is accompanied
by a backward displacement the osteotomy should take
place through the knee in order to bring the tibia
forward.

ARTHRODESIS, PSEUDARTHROSIS, AND ARTHROPLASTY

We frequently meet with a short fibrous ankylosis
which is painful when subjected to strain. In such a case
it may be necessary to substitute a bony ankylosis for a
fibrous one. This is done by arthrodesis, which is a
modified excision, and is most effective in the knee and
ankle. The procedure is called for most frequently in
adult tubercle, a condition not suitable for a mobilizing
operation such as arthroplasty or pseudarthrosis.

For painful monarticular osteo-arthritis of the hip,
already referred to, which cannot be dealt with conser-
vatively, an operative attack may be needed. An arthro-
desis will transform a weak painful joint which cannot
bear weight to a strong and painless limb. This opera-
tion, if effectively performed, is a serious one, as it
involves a complete disarticulation and a careful appposi-
tion of the denuded bones. It should be reserved, there-
fore, for the comparatively young and healthy, and should
not be performed on the weak or aged. An operation
which is very effective in these cases, and only takes
a few minutes to perform, is the oblique osteotomy intro-
duced by Lorenz for irreducible congenital hips, and
known as the "bifurcation operation." It is as success-
ful in monarticular osteo-arthritis as it is in ununited
fracture of the femur.

Many operations have been devised by which painless
motion may be retained.

INDICATIONS FOR MOBILIZING ANKYLOSED JOINTS

I shall not enter into any details of the various opera-
tions which have been employed in order to render
ankylosed joints mobile. Some consist in a reconstruction
of the joint, others consist of very free removal of bone
about the joint, with or without fascial interposition. In
other cases excision is performed, while in certain hips
where not only has the joint been destroyed, but massive
thickening of the peri-articular structures is present, it
may be advisable to remove an inch of the femur in its
upper third, fat or muscle being placed between the ends,
and so a very useful pseudarthrosis is secured. Details
of these various operations may be found in modern
orthopaedic textbooks. As technique improves the opera-
tive field increases, but even now we can offer suggestions
which will help us to decide whether we should try to
make an ankylosed joint mobile.

All who have had experience of arthroplasty are agreed that the most successful cases are those in which the ankylosis is bony, with comparatively normal-shaped bones. This will include traumatic joints, and those the result of pyaemia. We may exclude tuberculous joints, which so often and for years contain foci of infection.

The operation is contraindicated in the presence of active disease, and should be delayed until at least two years after its complete cessation. It should never be performed in the presence of sinuses, nor where the soft tissues are infiltrated and tense, nor where muscles are atrophied and adherent; nor should it be performed until growth is ended. The joint which responds most favourably to an arthroplasty is the elbow; the knee, although technique has improved, mainly by the excellent work of Putti, is still in the experimental stage. It is an operation which requires the highest judgement and skill on the part of the surgeon, and fortitude on the part of the patient, for the after-treatment is very painful. The elbow is a joint where we can almost promise a satisfactory result—good movement and fair stability; but the ankle-joint, if stiff and painless, should not be mobilized; if painful it should be arthrodesed.

AVERTIN IN GYNAECOLOGY

A RECORD OF 1,000 CASES

BY

JAMES YOUNG, D.S.O., M.D., F.R.C.S.ED., F.C.O.G.,

GYNAECOLOGIST, ROYAL INFIRMARY, EDINBURGH

In a previous paper I[1] have put on record the impressions gained after the employment of avertin in 345 unselected gynaecological operations. Our experience has now extended to over 1,000 cases, and increasing use has gone to confirm the view expressed in 1929 by Blomfield and Shipway[2] in their paper introducing avertin to British surgery that it is "a valuable addition to the drugs at the disposal of the anaesthetist."

The method of administration adopted is similar to that described in the previous communication and to that employed by other surgeons, and it is unnecessary here to enter into a detailed description. The procedure is very easily learned. The evening before the operation the bowel is washed out with an enema. One hour before, one-eighth of a grain of morphine is given hypodermically. Before removal from bed, the patient turns on the side and the drug in solution is slowly instilled into the rectum, the administration taking about fifteen minutes. Before the lapse of this period the patient is usually unconscious, the induction of the anaesthesia being smooth and pleasant. Throughout the induction and the period of unconsciousness the anaesthesia is strongly reminiscent of a deep natural sleep. On two or three occasions only have we found some mental excitement during the induction, while on three occasions the patients failed to pass over into complete unconsciousness. In all cases there is complete amnesia. The maximum anaesthesia is reached about thirty minutes after the commencement of the induction, and we plan that this interval will elapse before the operation is begun, although on many occasions, owing to the exigencies of the operating theatre, we have without disadvantage allowed over an hour to pass.

The drug is quickly absorbed from the rectum, but the dissolving fluid remains in the bowel for a longer time, and in the case of operations carried out in the lithotomy position it is apt to be squeezed out during the examination or the introduction of the speculum with a consequent soiling of the parts. To prevent this, it is our practice in such cases to withdraw the remaining fluid by means of a rubber catheter immediately before the commencement of the operation.

We employ, as a routine, a dosage of 0.1 gram per lb. of body weight. In very obese patients instead of giving the full ratio we employ a diminished dosage of 0.08 or 0.06 gram per kilo. We use the liquid preparation which contains 1 gram of avertin in each cubic centimetre, and by means of the chart supplied by the makers the respective quantities can be determined easily and rapidly. With this dosage the anaesthesia obtained is not profound, and, although sufficient often to allow of a minor procedure, such as curettage and, occasionally, of a plastic operation for vaginal prolapse, we find it an advantage as a routine to amplify it by means of ether given by the open method. The quantity of ether required is usually much less than that necessary for an unaided inhalation anaesthesia. It may now be claimed that the experience of many clinics engaged in all classes of surgical work has established that, when employed as a "basal anaesthetic" in such dosage as I have mentioned, avertin is a safe drug. During the early days fatalities were recorded, but there can be no doubt that these arose almost invariably from pushing the dosage to the stage of inducing a complete and self-sufficient anaesthesia.

ANALYSIS OF CASES

The drug has been used as the routine anaesthetic in my department during the period under review, and, except where on a few occasions a pelvic swelling—for example, fibroid tumour, pelvic abscess—has so encroached upon the rectum as to impose a mechanical obstacle to the instillation of the fluid, there has been no selection of cases. For this reason the experience can be accepted as representing that of an average gynaecological hospital practice in which, although much of the operating is of a minor nature, there is naturally at the same time a large admixture of grave and emergency material. Thus there were over 200 cases necessitating opening of the abdomen for the carrying out of hysterectomy (71), salpingo-oöphorectomy (24), ovariotomy (34) and removal of cysts with twisted pedicles (6), removal of the tube in ruptured tubal pregnancy (16), myomectomy for fibromyoma (10), appendicectomy (25), etc. There were 130 cases of plastic repair for vaginal prolapse. The age of the patients has varied from 5 to 76.

In the series there were five deaths, and in no instance could the fatal issue be attributed either directly or indirectly to the avertin.

The clinical data are briefly as follows:

1. K.117, 8-para, aged 58, was admitted in a collapsed state with complete acute inversion of uterus and vaginal prolapse associated with uterine fibroid. Death occurred twelve hours after hysterectomy.

2. R.156, 4-para, aged 40, with an abdominal swelling of a year's duration, was admitted with a history of vomiting, acute abdominal pain, and fever. Death occurred twenty-eight hours after operation, involving removal of an infected and adherent ovarian tumour.

3. D.762, 1-para, aged 40, was admitted for a marked degree of vaginal prolapse. There was a history of toxic goitre for fourteen years. She developed broncho-pneumonia four days after a modified plastic repair operation, and died ten days later.

4. I.366, 9-para, aged 40, was admitted with a history of breathlessness, menorrhagia, and, recently, of retention of urine. She collapsed four hours after removal of cystic fibroid by total hysterectomy, and died three hours later. The post-mortem revealed chronic toxic changes in the liver, and kidneys.

5. F.289. 1-para, aged 60, was a very obese patient weighing 18 stone, with very advanced and generalized abdominal carcinoma, probably originating in the uterine body. She died from heart failure thirteen days after exploratory curettage.

In addition to these five deaths, there was in hospital during the period under review one death after laparotomy and drainage of an abdominal abscess, which extended deeply into the pelvis, and in which ether anaesthesia was employed.

This mortality rate of 5 in 1,000, or 0.5 per cent., is much below our previous mortality rate of 34 in 1,799 consecutive cases, or 1.9 per cent., with ether, alone or in combination with chloroform, as the routine anaesthetic. We do not claim that in this reduction the sole part has been played by the employment of avertin, for it is possible to cite ways in which the general advance in our knowledge of gynaecological therapeusis within recent years has displaced surgery in favour of conservatism, and has thus contributed towards a saving of lives. During the period under review, for example, over forty cases of acute salpingitis (both gonococcal and streptococcal) were treated palliatively without mortality, and a large number of cases of intractable uterine haemorrhage were treated by non-operative means, such as radium, x rays, etc. By curtailing the necessity for recourse to major surgery these advances have necessarily tended to a general lowering of our mortality figures. Further, the recognition of the common part played by cervical infection in the production of low abdominal and iliac fossa pain, which at times may even assume acute characters, has, by improving our diagnostic weapons, reduced abdominal exploration for suspected appendicitis, tubal and ovarian disease, etc.[3] The greater insistence on a rigid pre-operative investigation and preparation, and in those cases in which post-operative infection is a special risk—for example, in vaginal prolapse—the prophylactic immunization of the patient with a streptococcal and *B. coli* vaccine, have also doubtless helped to reduce the post-operative morbidity and mortality.

After making all these allowances, however, we are convinced that the adoption of avertin as a basal anaesthetic has not only removed much of the distress formerly experienced by the patient, but has in a material way eliminated the risks incidental to all surgical procedures.

Advantages Claimed for Avertin

1. *Comfort of Induction.*—The importance of this factor cannot be overestimated. It is a matter of favourable comment by patients who have on previous occasions experienced other methods of anaesthesia. Apart from this softening of the memories of the operation day, however, we have the advantages accruing from the lessening of the pre-operative emotional stress. The work of Crile[4] and others has emphasized the importance of these questions by directing attention to the profound physical changes induced in the organism by emotion. The sleep induced before the patient leaves her bed implies that with avertin we have a simple and effective method of eliminating a whole series of dread-inspiring preliminaries—the tense expectation of the event, the arrival of the attendant to herald its approach, the agitation accompanying removal to the ante-room, and the administration of the anaesthetic. To many patients these circumstances constitute the most vivid memories of the operation, and it is a fact that the more acute sensibilities of women render them especially prone to such mental suffering.

2. *Reduction of Post-operative Distress and Morbidity.*—In ordinary circumstances the patient sleeps deeply for several hours after the operation, and thereafter for a considerable time the sensations remain dulled, so that the awaking to full consciousness, with its attendant discomfort and pain, is delayed often by many hours. Further, one of the most important of the advantages of avertin is the virtual elimination of the tendency to retching and sickness after the operation. The hospital ward following an operation day is now practically undisturbed in this respect, with the consequent removal of a grave source of distress, not only to the victims themselves, but also to the other patients, and with a consequent lessening of the work of the nursing staff. It cannot be denied that the relief brought in these ways to the patient in the immediate post-operative phase must imply, in addition, a reduction in the risk to life and health. The abolition of the straining incidental to vomiting by leaving the wounds undisturbed diminishes the chance of haemorrhage and sepsis. The importance of these advantages can hardly be overestimated in regard to laparotomy and pelvic floor wounds. Dandy[5] has recently called attention to the same benefits which avertin confers in major brain surgery.

3. *Reduction of Post-operative Pulmonary Complications.*—Post-operative bronchitis and pneumonia, formerly a not infrequent source of anxiety and danger, have been reduced. In a total of 203 cases in which opening of the abdomen was carried out there has been an entire absence of such post-operative pulmonary troubles. Altogether, in the series of 1,000 cases, there have been three instances of mild bronchitis, one of pleurisy, and three of broncho-pneumonia. There was one death from broncho-pneumonia, which developed after a plastic operation for prolapse in a woman with toxic goitre. It is at first sight rather remarkable that, although we employ ether so consistently in conjunction with avertin, we have had only one death from broncho-pneumonia in this large series. The lessened quantity of the inhalation anaesthetic required after avertin plays, of course, an important part. We have come to the conclusion that of equal, if not of greater, moment is the fact that the smoothness of the induction and the elimination of retching, both during the course of the operation and the early post-operative phase, lead to a wholesale reduction in the risk of septic inhalation. Many other observers have referred to the infrequency of pulmonary complications after the employment of avertin. For example, Dandy[5] recently has recorded "250 major cranial operations of every type without mortality from the anaesthetic, no post-operative pneumonia, and no deleterious effect immediate or remote." Dandy believes that with avertin there is a reduction in the risk of aspiration of gross septic material into the lungs. Wülfing,[6] in a recent paper, based on a record of 1,200 cases, refers to the same facts, and states that in his series pulmonary troubles have been fewer and less severe than with ordinary inhalation anaesthesia. The diminished risk of pulmonary irritation makes avertin of special value where anaesthesia is contemplated in patients already suffering from bronchitis, asthma, etc.

It should further be noted that in our series there have been no cases of acute dilatation of the stomach or paralytic ileus. It is possible that the absence of these complications is to be related to the use of avertin, although on this question further data are necessary.

Disadvantages of Avertin

1. *Lowering of Blood Pressure.*—This constitutes one of the most striking effects of avertin. We have found that a systolic drop of 20 to 30 mm. Hg is not uncommon, and in cases of hypertension the fall may be as great as 100 mm. Hg. It commences with induction and usually reaches its maximum within fifteen to twenty minutes. Dr. W. P. Kennedy, working in my department, has subjected the blood pressure during avertin anaesthesia to a close study in 150 cases, and has published the results in the *British Journal of Anaesthesia*.[7] This paper should

be consulted by those interested. In this place it may be stated that our conclusions are that the fall in blood pressure is of no practical significance. Even in the cases showing the maximum drop the general condition has not given rise to any anxiety. In many cases we have noted that the pressure is quickly restored spontaneously or after the administration of the ether is begun. It is quickly readjusted by the hypodermic injection of 1/2 c.cm. of a solution of ephedrine hydrochloride (50 mg. per c.cm.), and this we utilized commonly during our early experience, although, since recognizing that the condition is clinically unimportant, we are now using drugs less and less. Our findings in these respects are paralleled by those of other workers (for example Dandy).

2. *Depression of Respiration.*—Slowing and reduction in the amplitude of respiration are common, and this effect at first gave us some concern. We have, however, seen no harm arise from it. Where severe, it is at once readjusted by administering carbon dioxide. For this purpose we find it advisable that a cylinder of oxygen containing 5 per cent. CO_2 should always be at hand in the theatre.

A minor disadvantage of avertin is the headache of which a considerable proportion of patients complain on waking from the anaesthetic. It is readily controlled by pyramidon 5 grains (repeated after four hours if necessary, although one dose usually suffices).

CONCLUSIONS

1. Employed in a dosage which does not exceed 0.1 gram per kilo of body weight, avertin is a safe drug. In this dosage it may suffice for minor operative work, but a supplementary inhalation anaesthesia is usually required.

2. Its advantages are: (*a*) ease, comfort, and certainty of induction; (*b*) reduction of post-operative discomfort and sickness; (*c*) reduction of post-operative pulmonary complications.

3. In this series of 1,000 unselected cases there have been no deleterious effects, either immediate or remote.

4. There have been five deaths in the series, and in no instance could the fatal issue be attributed to the avertin.

SOME SIALOGRAMS

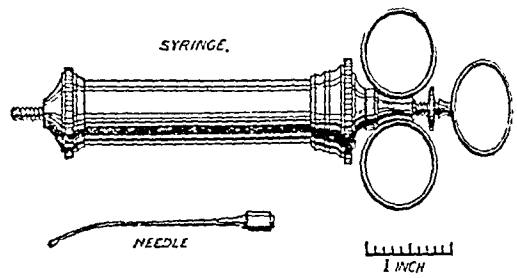
BY

L. N. PYRAH, M.Sc., CH.M., F.R.C.S.,

AND

P. R. ALLISON, B.Sc., M.B., M.R.C.S.,

(From the Department of Surgery in the University and the General Infirmary at Leeds)



(*With Special Plate*)

Lipiodol radiography has become an extremely useful diagnostic procedure during the last few years. Lipiodol came into its own quite early in the diagnosis of diseases of the chest, tumours of the spinal cord, and sterility. It is an oil containing about 50 per cent. of iodine, and is therefore highly opaque to *x* rays. It is non-toxic, and is only absorbed in small amounts, while the firm nature of its iodine union renders it very unlikely that any patient in whom it is used will develop iodism.

Sialography has been little used because the cases upon which it can throw light are very few; but in a limited number of cases, facts of both diagnostic and pathological interest can be obtained from the study of a sialogram. During the war, sialography was frequently used for the investigation of salivary fistulae. Both parotid and submaxillary glands have easily accessible ducts, so that the technique is not difficult.

TECHNIQUE AND *X*-RAY METHODS

The lipiodol injection is carried out by means of a metal syringe fitted with a plunger, also of metal, as shown in the accompanying sketch. The stem of the plunger is graduated in cubic centimetres, so that the amount of lipiodol injected can be measured. The needle

is a modified lachrymal duct needle made of silver, and has a blunt, slightly bulbous end; it is malleable, so that the curve can be adjusted to suit any given case. The needle is fitted to the body of the syringe by a screw attachment. There is therefore no risk of the patient's mouth being coated with lipiodol from the sudden detachment of the needle during the process of injection. With gentle usage no harm can be done to the lining membrane of the salivary duct. The plunger is fitted with a ring for the surgeon's thumb, and the body of the syringe has two rings for the index and middle fingers. The instrument is thus very easily controlled. The usual precautions of warming the syringe, needle, and lipiodol are taken; there is then no difficulty in driving the lipiodol through the rather fine-bore needle. In our hands the syringe has proved eminently satisfactory. Payne[1] has obtained good results by the use of a simple glass syringe.

Parotid Gland.—The injection is performed with the patient sitting facing the surgeon, in a good light. In injecting the right Stenson's duct, the surgeon retracts the right cheek with his left thumb and forefinger, and looks for the orifice of the duct, which is situated opposite the crown of the second upper molar tooth. The opening in most people is slit-like; in some it is situated on a slight papillary elevation. If there is difficulty in finding the orifice, the gland may be made to secrete by giving the patient a slice of lemon, or simple pressure upon the gland may expel a few drops of saliva and enable the opening to be found. The needle of the loaded syringe is brought up to the orifice of the duct and is steadied by the surgeon resting it upon his left thumb. It is then into the duct for about an inch. The introduction of the needle causes a slight cutting pain, but not sufficiently intense to cause undue discomfort.

The injection is continued gently until the patient experiences a sensation of discomfort in the region of the parotid gland; this indicates that the finer ducts are filled with lipiodol. About 1/2 to 1 c.cm. is used. The needle is quickly but gently withdrawn, and the patient is immediately placed in the recumbent position on the *x*-ray table. One of us (P. R. A.) was able to inject his own Stenson's duct while standing in front of a mirror in a good light. In none of our cases has any untoward complication occurred as a result of injection.

Submaxillary Gland.—The injection is performed in a similar manner. The patient sits with the mouth wide

open and with the tongue pressed firmly upwards against the hard palate behind the upper incisor teeth. The orifices of Wharton's ducts are situated side by side near the fraenum linguae on a well-marked papilla. The needle is introduced as before, but the procedure usually presents more difficulty than in the case of the parotid duct.

X-RAY TECHNIQUE

Parotid Gland.—The patient lies on his side, and the radiographer places the head (as accurately as possible) in the lateral position, so that the two rami of the lower jaw are superimposed. The head is hyperextended so as to open up the space between the jaw and the vertebral column. The mouth is opened and is retained in this position by a cork, which is placed between the incisor teeth. With the patient in this position, the greater part of the shadow of the gland is in front of the shadow of the cervical vertebrae.

Submaxillary Gland.—A lateral radiogram is taken here. The patient's mouth is fully opened and the tongue is pressed upwards to the roof of the mouth. There is usually no shadow of bone overlying that of the gland, but in some cases the hyoid shadow may be superimposed.

USES OF SIALOGRAPHY

1. In some cases of chronic parotitis with subacute exacerbation, sialography reveals that one essential feature in the pathology of the disease is a dilatation of the ducts and of the alveoli.

2. A sialogram is of value in helping to decide whether a tumour in the neighbourhood of a salivary gland is derived from the gland tissue or from adjoining structures. In the former case the gland may be largely destroyed and there may be a considerable filling defect on the sialogram, while in the latter case, even though the gland may be somewhat displaced, it will show normal filling.

3. Injection of lipiodol may be of assistance in the localization of calculi.

4. The precise position and track of a salivary fistula, more especially of the parotid gland, can be traced very easily by means of a sialogram.

NORMAL SIALOGRAMS

Parotid Gland.—By the study of the sialograms of the normal parotid glands which we have so far taken, it would appear that Stenson's duct is formed about the middle of the posterior border of the ramus of the lower jaw by the union of two other ducts of slightly smaller diameter; these pass upwards and downwards respectively, and join Stenson's duct at a right angle. During its course across the face it is joined by five or six very small ductules from the socia parotidis and from the anterior lobules of the gland. At the point where it curves forwards in front of the masseter it is often compressed by the anterior border of that muscle, and the shadow of the lipiodol here is considerably attenuated; the otherwise even course of the duct shows at this point a slight kink. The two intra-glandular ducts run upwards and downwards to the upper and lower poles of the gland respectively, and are joined by numerous smaller collecting ducts. These in turn are formed from an arborization of fine ductules, which are the terminal ducts and alveoli. In a normal sialogram the alveoli show no dilatation, but are represented by the tiny endings of the smallest ducts. The gland reaches below to the angle of the jaw and above to the neck of the mandible.

Submaxillary Gland.—From Fig. 3, it would appear that the intra-glandular portion of Wharton's duct commences at the lowest point of the gland, one and a half inches below the lower border of the body of the mandible and one and a half inches in front of the angle of the jaw. It passes vertically upwards to a point in the submaxillary fossa, about a quarter of an inch above the lower border of the body of the mandible. At this point the duct turns sharply upwards and forwards to the papilla on the floor of the mouth. The figures given will vary to some extent with slight changes in position of the patient's head during radiography. Both sides of the main duct receive smaller ducts, which are themselves made up of a fine arborization of tiny ductules from the lobules. One rather larger tributary passes downwards and forwards from the posterior part of the floor of the mouth to join Wharton's duct at the angle mentioned.

CASE REPORTS

CASE I.—*Bilateral Chronic Parotitis with Subacute Exacerbations*

History.—M. H., female, aged 16. This patient was first seen in 1927, when she came to hospital complaining of a discharge of pus from the left ear. A few months later there appeared a gradual swelling of the left parotid gland, followed a few weeks afterwards by a similar swelling on the right side. At first the swellings were slight and not painful. In July, 1927, the right parotid gland suddenly became painful, red, and hot, and in a few days' time similar changes occurred in the left gland. There was no rise of temperature and of pulse rate, though the girl felt ill and had no appetite. The swellings remained in this condition for several days, but subsided as a result of treatment by fomentation and hot mouth washes. During the following four years the patient has had both glands persistently larger than normal, with occasional bilateral acute exacerbations, precisely as in the first attack. In some of the acute attacks she noticed an excessive discharge of saliva containing some solid debris; in others, the saliva was thick and purulent, and of a disagreeable taste and offensive smell. These changes subsided with the passing of the acute attack. There has been no history of a sore throat or of other illness.

Examination.—During the chronic stage both parotid glands are slightly but definitely enlarged. The surface is lobulated throughout, each lobule being an enlarged single alveolus of the gland. The gland is neither hot nor red, nor is it tender. On pressure, clear saliva can be expressed from the gland. During the acute attack the gland is much more enlarged; it is hot to the touch and tender on pressure, but there is no fluctuation. The surface, which in the chronic stage was lobulated, now becomes quite smooth. On gentle pressure over the gland, saliva containing plugs of pus mixed with epithelial debris can be squeezed out of Stenson's duct in considerable quantity. By this procedure the feeling of tension present in the gland is relieved. At no time has there been any evidence of gross abscess formation, and the condition has resumed its chronic state in from one to three weeks' time. The orifice of Stenson's duct was on some occasions reddened and slightly more prominent than usual, though this was not uniformly the case. The first teeth were healthy, but the second dentition is very unhealthy; the teeth are deficient in enamel, and several have been broken off near the alveolar margins; many of the remainder are carious. The throat and tonsils are healthy. The discharge from the ear has subsided in the last three years. General examination of the patient reveals nothing abnormal. The blood count is normal and the Wassermann reaction is negative. A possibility of parotid calculus led to repeated x-ray examinations, all of which were negative. A probe could be introduced into either duct without encountering any obstruction. A culture from the debris discharged from the right Stenson's duct yielded on one occasion a staphylococcus. The debris was found to consist of desquamated epithelial cells, pus cells, and much mucus.

Sialogram.—The injection of lipiodol was very easily effected. The gland is moderately enlarged. The lumen of Stenson's duct is considerably wider than normal, and each terminal ramification is very much dilated. The picture is very like that obtained after lipiodol injection into the trachea in a well-marked case of bronchiectasis. The sialogram here seems to indicate that the disease is largely an affection of the ducts. Probably the swelling and oedema of the walls of the

smaller ducts cause some obstruction to the outflow of saliva, with consequent dilatation of the alveoli.

Treatment.—The patient has been given dental treatment. She has had a long course of potassium iodide without result. She has received the greatest benefit from regular massage to both glands; this the patient has done for herself after meals for the past few months.

CASE II.—*Chronic Sialadenitis of the Submaxillary Gland*

History.—A. B., female, aged 29 years. The patient was first seen on admission to hospital, under the care of Mr. Flint, in August, 1931. During childhood she had had recurrent lumps immediately below the lower jaw. These used to appear, remain for a few weeks, and then gradually subside, only to recur again after a variable interval. They were hard in consistency and painful to touch; movements of the jaw also caused great discomfort. At the age of 13 her tonsils were removed, and the lumps did not appear again until 1927, twelve years later. In that year the patient noticed a small tumour on the left side of the neck, just below the lower jaw, which varied in size and became swollen and painful after meals. She also complained of a pricking sensation underneath the tongue, and on several occasions had managed to squeeze out from the floor of the mouth stones which were hard, gritty, and the size of a small pea. A fortnight prior to admission the tumour increased in size. It became very tense and tender, and caused considerable pain both in the neck and in the left ear. At no time throughout the illness had there been any suggestion of involvement of the other salivary glands.

Examination.—On admission to hospital the patient had a large swelling below the lower jaw, which extended from the mid-line anteriorly to the angle of the mandible posteriorly. The skin over it looked tense and glossy. There was marked fetor of the breath. The tumour was of a hard, elastic consistency, and was fairly regular in outline; it bulged upwards into the floor of the mouth on the left side of the frenum linguae. During the acute attack it was tender to the touch. Inside the mouth the opening of Wharton's duct was seen to be ragged and inflamed, and a small, white, flake-like calculus was found adhering to the edge of the opening; this was easily removed. About half an inch posterior to the papillary eminence on which the duct opened, there was a fistulous communication between the duct and the mouth, and from this opalescent saliva was ejected at intervals.

Sialogram.—The needle was inserted through the fistula already described, and was passed backwards along the duct without obstruction. About 1/2 c.cm. of lipiodol was injected; of this a small quantity escaped backwards into the mouth. In the sialogram the duct from the gland to the

CASE IV.—*Acute Parotid Abscess*

History.—A. H., female, aged 45 years. They [illegible] admitted to hospital in July, 1931, with an [illegible] in the left parotid region, of three days' duration. [illegible] ness began with sharp lancinating pains behind the jaw, and when the patient reached hospital [illegible] ing intense pain. There had been no discharge [illegible] mouth and no history suggesting the passing of [illegible] She also complained of a numbness of the left side of the [illegible] completely obliterated by a large inflammatory [illegible] the parotid region, with much surrounding oedema. [illegible] eyelids were so swollen that the eye was quite invisible. In addition to which there was a paresis of the whole of the left side of the face. Nothing abnormal was noted inside the mouth, but there was a purulent discharge from the left [illegible] which on closer inspection was found to issue from an inflammatory area on the anterior wall of the external auditory meatus. The swelling was hot and extremely tender, and gentle pressure over the parotid caused pus to issue from the external meatus in increasing quantities. There was much oedema and swelling in the neck, and this caused some difficulty in breathing

Treatment.—An incision was made just behind the angle of the jaw on the left side, and a pair of forceps was pushed upwards into the parotid region. A large collection of pus was found and liberated, and a tube was inserted into the abscess cavity. As a result of this treatment the condition rapidly subsided and the facial paresis recovered completely. When seen a month later the swelling had entirely disappeared, although the parotid region was still tender. There was a slight serous discharge from the incision behind the angle of the jaw, and a muco-purulent discharge from the external auditory meatus showed two polypi. Inspection of the external auditory meatus showed two polypi on the anterior wall, and pus was seen to be discharging from this point. The polypi were removed, and histological examination proved them to be composed of simple granulation tissue. A sialogram was taken at this stage.

Sialogram.—Stenson's duct appears normal. There is almost complete absence of the contributory ducts owing to destruction of the gland by the acute inflammatory process.

We wish to thank Mr. J. F. Dobson and Mr. E. R. [illegible] for permission to publish these cases, also Mr. Harrison for drawing of the syringe, and the members of the [illegible] who have given invaluable help and advice.

maxillar as possible for me to recognize a case of atient's erticulitis with tolerable certainty, as a pwar I had diagnosed diverticulitis with the sha enema, the patient developed an acute e ca

a Norwegian air pilot, aged 40, came to see ar 29th, 1930. He had had some pain in domen for ten days previously. For the first the pain was not bad, but for the last two days severe and kept him awake all night. It came some of them being so severe as to double him him shout. The pain was not related to food, longed to eat lest it came on again. His appetite ar it, and he felt quite comfortable in the intervals from tacks. He had had similar pains about one year form Norway, but was put on a "diet," and had er trouble

ere r attacks he found it painful to urinate. He had m, micturition by day, and at night waked once or nay is also somewhat constipated. His tongue was ere was definite tenderness in the lower abdomen, ject fossae, and in the middle line. The liver and the not palpable. He had large external haemorrhoids h was normal

h ordered an enema, which made him more comfort- The following day he was given a barium enema, which that the pelvic colon was markedly pulled over to the iac fossa, and a number of diverticula were seen. He en given a barium meal, after twenty-four hours, exam- again revealed the presence of multiple diverticula sigmoid flexure pulled over to the right. I therefore the diagnosis of diverticulitis with adhesions of the colon to structures in the right iliac fossa. This was mber 31st, 1930. His pains had greatly diminished, was feeling quite well

m on January 2nd, 1931, his pains came on again, ith much greater severity. He vomited twice, and d to see him at 2 p.m. He had a temperature of his pulse was 100. There was great tenderness and dity of the lower abdomen, particularly on the He looked ill, and there was little doubt that he te abdomen. Armed with the x-rays, I diagnosed ve diverticulitis. Mr Lindsay Sanders was immed- led in. He agreed with the diagnosis, and operated evening. On entering the abdomen a large quantity as immediately seen. A thickened, boggy loop of on was found in the right iliac fossa, with a perfora- diverticulum. A number of other diverticula of the were also readily seen. The perforation was carefully he pelvic colon brought back to the left iliac fossa, abdomen drained. The patient made a complete

is x-rayed again (barium enema) on February 13th, en the loop of the pelvic colon was then seen in the fossa. Numerous diverticula were still visible in the olon. The next barium enema flowed well, showing no tion at the site of perforation, although the loop of on seemed bound down with adhesions.

COMMENTARY

Certain points of interest emerge from a consideration of the above case:

1. The fact that a barium enema examination was performed and a diverticulitis diagnosed a few days before its perforation.

2. The patient was quite well for three days after the barium enema examination, so that it cannot be held responsible for influencing the perforation.

3. Perforation of the sigmoid colon is generally fraught with grave danger, as the contents are notoriously septic. Immediate operation in the above case was followed by a complete recovery.

I wish to record my thanks to Mr Lindsay Sanders for the manner in which he performed an admirable operation with great success.

A CALCULUS IN AN ECTOPIC KIDNEY

BY

J. LLEWELLYN DAVIES, M.B., F.R.C.S.

HONORARY ASSISTANT SURGEON IN CHARGE OF CASUALTY DEPARTMENT, NOTTINGHAM GENERAL HOSPITAL

(*With Special Plate*)

A woman, aged 34, was admitted, in July, 1929, to the Nottingham General Hospital, under the care of Mr F. C. Greig, complaining of abdominal pain and increased frequency of micturition, which had persisted during the past three years. The pain was referred to the lumbar region, to the left iliac fossa, and at times was said to shoot down the inner side of the right thigh. It was usually aching in character, was made worse by exercise, but was relieved by rest. Increased frequency of micturition had recently become very marked, amounting to twelve times during the day and three times at night. For the past eighteen months the act had been painless. About three years ago, for three weeks, haematuria was severe, but since then no blood has been noticed. Seven years ago hysterectomy was done, but no details are available.

On examination the woman appeared to be in fairly good health. There was some tenderness deep to the upper half of the median suprapubic operation scar. The right kidney could not be felt; the lower pole of the left was palpable. The urine was alkaline, and contained pus. An x-ray photograph of the pelvis is reproduced in Fig. 1 (on Plate), and shows an unusual object situated in front of the sacrum.

At Mr Greig's request I carried out a urological investigation. The cystogram reproduced in Fig. 2 proves that the object seen in Fig. 1 is situated above and distinct from the bladder. Cystoscopy revealed a normal bladder and left ureteric orifice, but the right ureteric orifice was red and oedematous, emitting only an occasional sluggish purulent efflux. After intravenous indigo-carmine, there were copious well-coloured efflux from the left side in six minutes, but no dye appeared on the right side after fifteen minutes. A catheter passed up the left ureter easily, but could be introduced only a few centimetres on the right side. The pyelogram of the left kidney is normal. On the right side the catheter has passed inwards towards the promontory of the sacrum, and in one film a little of the pyelographic medium can be seen to have passed down on to the object in the pelvis.

The diagnosis suggested was a dendritic calculus in an ectopic kidney, and nephrectomy was advised.

Mr Greig opened the abdomen through a suprapubic paramedian incision, and found the kidney fixed retroperitoneally in the hollow of the sacrum, with a coil of ileum partly covering it and firmly adherent. The pelvis of the kidney was lying anteriorly with the ureter coming off it and passing down to the right side of the bladder. The renal artery was defined with difficulty owing to the perinephritis, and whether it arose from the right common

iliac artery or from the aorta could not be determined. The kidney was full of phosphatic calculi (Fig. 4).

The woman was considerably shocked by the operation, which was very difficult owing to the firm adhesions, but she made a good recovery, and two years later was reported to be in good health.

COMMENTARY

It is an interesting subject for speculation why the left renal bud developed normally from the Wolffian duct and rose to the lumbar region, whereas the right renal bud, although it grew into a kidney, did not migrate from the site of its origin at the level of the second sacral vertebra.

This case furnishes another example of the common observation that organs congenitally misplaced are more liable to disease.

My grateful thanks are due to Mr. Greig for permission to publish this account, also to Dr. Clayton Rigby and his staff for the *x*-ray films, and to Dr. A. Gordon for the photograph of the specimen.

ENCYSTED EMPYEMA

BY

N. D. PATEL, M.D., M.R.C.P.

(With Special Plate)

Encysted empyemas are not very rare conditions. They are difficult to diagnose without the help of *x* rays, lipiodol, exploratory needle, or artificial pneumothorax. Before the introduction of these special methods of investigation they were often missed during life, the diagnosis being only made at the necropsy. The collection of pus, often pneumococcal, but sometimes tuberculous, may occur in one of the interlobar fissures, between the diaphragm and the under surface of the base of the lung, between the lung and the pericardium, or in the general pleural cavity, in the pockets formed by the adhesions of the parietal and the visceral layers of the pleura.

The following case showed a collection of pus between the lung and the right margin of the heart, and is, I think, sufficiently rare and interesting to be put on record.

R. C., a married woman, aged 28, was suffering from intermittent fever, cough, and progressive loss of weight, for about ten months, when I saw her on June 7th, 1931.

HISTORY

The history was that about a year ago she had pneumonia in the right lung following delivery. For about two months after the attack of pneumonia she remained quite well. Then she had an attack of diarrhoea, which lasted for a few days. Some days later she had a rise of temperature with rigor, and ever since she had an intermittent pyrexia (during the last eight months). For the first month or two, shivering and perspiration were frequently present. For the last four months, she had a slight hacking cough, which was, in her opinion, due to something at the back of her throat rather than in the chest. There was very little sputum. She complained of a nasty taste and stickiness in the mouth. She had lost considerably in weight—36 lb. in the last ten months.

Except for the attack of pneumonia twelve months ago, her previous health had been quite good. She had six children, five of whom had died in infancy; one was alive and well. Her appetite was good, she slept well, and her bowels were regular, though at times loose. She had had amenorrhoea for the last seven months. Her family doctor was treating her for pulmonary tuberculosis, and had sent her to Panchgari, a hill station near Bombay, popular with tuberculous patients. She stayed there for a month under the care of a specialist, but her condition got worse, and she returned to Bombay.

EXAMINATION

On examination she was found to be anaemic, wasted, and obviously in a toxic state. The fingers were tapering, parrot-beak type, and showed early clubbing. Her breath was foul, and there was pyorrhoea alveolaris. Her temperature was 102° and the pulse rate was 100 per minute.

Examination of the lungs revealed nothing abnormal, except a few rhonchi in both lungs. The cardio-vascular, abdominal and nervous systems showed nothing amiss. The liver and the spleen were not palpable.

Blood examinations carried out on several occasions showed no malaria parasites. There was a secondary anaemia, the red blood cells being 3,500,000 per c.mm. and haemoglobin 55 per cent. There was also a moderate leucocytosis, the white cells being 13,500 per c.mm. The Wassermann reaction was negative.

Sputum, though scanty, was repeatedly examined for the presence of tubercle bacilli, but all examinations were negative.

Examination of the urine showed the presence of a pyuria. It was acid in reaction, and contained albumin and pus. A catheter specimen showed pus cells, *B. coli*, and staphylococci. The culture of urine showed these organisms and a pure growth of pneumococcus. No tubercle bacilli were seen and inoculation in a guinea-pig also proved negative. An *x*-ray examination of the urinary tract did not show any abnormality.

X-ray examination of the chest showed that the heart was normal in size and in position. The lungs also showed no lesions but a triangular shadow opposite the right second and third costal cartilages just above the right border of the heart. It was homogeneous, and had clearly defined margins (Fig. 1, on Plate). Three weeks later, an *x*-ray picture was taken after injection of lipiodol. It shows up the round mass clearly, and at the same time gives an excellent picture of the normal bronchial tree (Fig. 2). The shadow suggested an enlarged mediastinal gland, either tuberculous or Hodgkin's disease, a cold abscess, a cyst, a neoplasm, or an encysted empyema.

The patient was treated for pyelitis with large doses of alkalis by the mouth, neotropine, and cylotropine injections in turn. By this treatment fever could be controlled and pus in the urine reduced, but only for a time, presumably because the kidneys were only acting as a filter, the focus of infection being in the lung.

DIAGNOSIS

Pyrexia of long duration, coming on after an attack of pneumonia, the obviously ill and septic look of the patient, clubbing of the fingers, leucocytosis, and the *x*-ray appearances of the chest suggested a collection of pus in the chest, and the diagnosis of an encysted empyema was made. Absence of the local physical signs in the chest was explained by the small size and situation of the empyema. As the patient was not getting any better, surgical intervention was considered, but she refused operation, and discharged herself after a month's stay in the hospital.

As the collection of pus is very small and so near the lung bronchi, it is to be hoped that it will either get absorbed or that it will rupture into the bronchus and be coughed up.

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

THE SELVAGE STITCH

One of the most annoying occurrences to the surgeon is the peritoneum which will not hold sutures. This is especially trying when there is some difficulty also with the anaesthetic and the patient is not properly under. The abdominal muscles are rigid, and the peritoneum retracts far under the edge of the wound on either side. Attempts to draw it together result in a series of tears until the edge looks like a fringe. The paramedian incision, with displacement of the rectus outwards, makes it even more troublesome owing to the overlap of the muscle.

One solution is to obtain better anaesthesia; but there still remain those cases in which the patient does not take the anaesthetic well, and the abdominal wall is more or less rigid with retraction of the peritoneum; or the

peritoneum is of gossamer-like texture, and extremely difficult to suture without tearing, even with good relaxation; or, as in the case of large incisional hernia, the peritoneum is sound enough, but there is a wide gap, and considerable force has to be used to get the peritoneal edges together.

The following simple method which I have devised is so effective that I am sure it will be found a "stitch in time" If it has ever been described before, I am not aware of it.

Instead of making any attempt to suture the two edges of the peritoneum, take a long piece of No 2 catgut on a round needle and, commencing at one end of the wound, oversew the edge from one end to the other (Fig. 1). Arriving at the

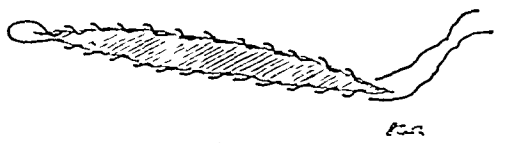

Fig. 1.

other end, a loop is left and held in forceps The suture is continued along the other edge to the point of commencement where the two ends of the suture are grasped in a second pair of forceps (Fig 2) The two pairs of forceps are now

Fig. 2.

pulled upwards and apart by the assistant to make longitudinal traction on the edges of the peritoneum. The selvage stitch obtains a spiral grip of the edge of the peritoneum—the greater the longitudinal traction the firmer the grip.

The usual peritoneal suture is now commenced, and by keeping the needle as close as possible to the outer side of the catgut forming the selvage stitch there is no further splitting, however hard the suture is drawn (Fig 3) There

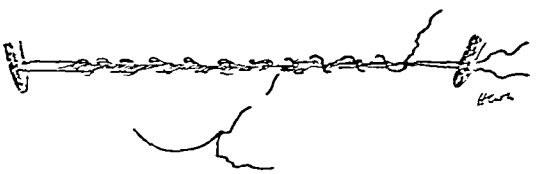

Fig 3.

is no necessity to tie the selvage stitch at the ends of the wound, it has done its work when the peritoneal suture is completed and is, of course, tightly held by it

Liverpool H. C. W. Nuttall, F.R.C.S.

CARCINOMA OF CERVIX WITH TWIN PREGNANCY AND NORMAL DELIVERY

Cases of carcinoma of the cervix and pregnancy with delivery *per vias naturales* have been recorded. Generally these have been diagnosed before delivery, and if not terminated by Caesarean hysterectomy there has been severe post partum haemorrhage. In 1913 Mylvaganam[1] reported a case of advanced carcinoma of the cervix uteri containing twins, treated by vaginal hysterectomy at the fifth month In this case pregnancy was not diagnosed, the foetuses being discovered only at operation. The indication for operation was the severe haemorrhages. In 1918 B. P. Watson[2] reported a case of cancer of the cervix complicating triplet pregnancy, treated by Caesarean Wertheim hysterectomy at the fifth month. Pregnancy was diagnosed, but from the second month haemorrhages and foul vaginal discharge were present. The following case appears to be unique, as I have failed to find a similar one recorded in the literature.

I was called in by a midwife to Mrs. B., aged 38, a 2-para, on account of a prolonged first stage. The history of the pregnancy was uneventful except for a certain amount of low backache. There was no history of offensive discharge or of bleeding The last menstrual period had commenced on September 23rd, 1930, had lasted five days, and labour had begun on April 27th, 1931. There had been a show, but the pains were slight and infrequent

On examination the abdomen was seen to be very pendulous. Twins were easily diagnosed On vaginal examination the os was the size of a half-crown It was noticed that the cervix was hard and irregular in outline. No ulcer was felt, and there was no bleeding on examination

In view of these findings, and the absence of any history pointing to carcinoma, I took the condition of the cervix to be due to the scarring of lacerations at the first confinement. This would also explain the slow dilatation I gave a hypodermic injection of morphine 1/4 grain and hyoscine 1/100 grain. There was very little progress for twenty-four hours At 1 30 a.m. on April 29th a live female child was born (vertex), followed by a live male child (breech) three hours later There was no difficulty in delivery, and there were two independent placentae There was some brisk post-partum haemorrhage, but this was easily controlled by injection of pituitrin 1 c.cm

The infants were premature and tongue-tied. The fraenum linguae was incised, and by the third day they were able to suckle. The mother developed a temperature of 101° F. and a pulse rate of 116 on the third day She also had herpes labialis. The next day the temperature was normal. On the fifth day the male infant developed bullous impetigo (pemphigus neonatorum), and, despite vigorous antiseptic treatment, died on the eighth day The female infant developed pemphigus on the sixth day, and died on the ninth day The mother, whose condition, except for extreme lassitude, was normal, got up on the tenth day Her lochia had been normal. On the thirteenth day she took to her bed again. On the fourteenth day she developed pulmonary oedema, became comatose, and died Post-mortem examination showed carcinoma of the cervix with glandular deposits.

The interesting points in this case are.

1. The absence of any symptoms of carcinoma during the pregnancy—for example, haemorrhages or blood-stained discharges.
2. The absence of severe post-partum haemorrhage, a possible complication, which the textbooks stress as an indication for Caesarean hysterectomy.
3. The viability of the infants.
4. The probable infection of the infants with pemphigus from the carcinomatous area.

British Medical Association

CLINICAL AND SCIENTIFIC PROCEEDINGS

SOUTHERN BRANCH: PORTSMOUTH DIVISION

Indications for Exploration of the Abdomen

The second scientific meeting of the session of the Portsmouth Division was held at Southsea on November 12th, with Dr McAskie in the chair.

Mr. Zachary Cope delivered an address on the indications for exploration of the abdomen He began by remarking that the number of abdominal explorations—opening the abdomen because of unexplained symptoms—was diminishing with the progress of knowledge The pioneer work in the twenty years following 1880, when such exploratory work really began, ushered in a period of clearer definition of many of the clinical pictures, and of more scientific methods of diagnosis It was now

exceptional for the abdomen to be opened without the surgeon having a fairly approximate idea of the condition he was going to find. The introduction of radiology had rendered it habitually possible to see the silhouette of the crater of a gastric ulcer, the shape and size of the renal pelvis; to detect constriction of the gut at the oesophagus, pylorus, or colon; to estimate the degree of obstruction of the cystic duct; and to give an assured and definite opinion as to the presence in the abdomen of calcified glands or an early foetus—not to mention the various forms of stone in the renal and biliary tracts. Radiological exploration constituted a bloodless and almost painless abdominal exploration, though on occasions it was still regrettably neglected. Test meals, blood examinations, biliary drainage, and the biochemical investigation of renal function had greatly helped; but, despite the assistance of various instruments for seeing the interior of cavities, such as the cystoscope and sigmoidoscope, considerable territory was still unexplored.

The indications for exploration in chronic conditions must be carefully distinguished from those in acute disease when certain methods could not be used. Generally speaking, if all the usual diagnostic methods had been unsuccessfully tried in a chronic case with obscure abdominal symptoms giving rise to anxiety, exploration was advisable. There were three groups of such cases. In the first there was obviously some anatomical alteration within the abdomen—for example, a tumour. It was particularly difficult to determine the nature of certain swellings, as in the case of some glandular enlargements, tumours arising in the retroperitoneal tissues, hydatid growths, secondary malignant deposits in the peritoneum, and some tuberculous masses. Moreover, when a chronic septic focus or abscess persisted until such time as the original acute attack had been forgotten, only exploration could differentiate it from a mass due to malignant disease. A chronic septic abscess (as from a perforated appendix) might be unattended by fever or noticeable leucocytosis. Tumours in the abdomen might portend serious trouble, and their nature should never be left in doubt. Diagnosis of ascitic accumulation might be impossible without abdominal exploration. Common causes were hepatic disease, tuberculous peritonitis, and malignant deposits on the peritoneum. All the necessary information could be obtained through a small incision under local anaesthesia. Mr. Cope then described an instrument he had devised for intra-abdominal examination through a one-inch incision. Another group of cases comprised those of serious physiological derangement, which might be due to organic disease amenable to surgical treatment. Jaundice, persisting for some weeks, might necessitate exploration if no tumour could be felt and a cholecystogram provided negative evidence of gall-bladder disease. If persistent and painlessly increasing, carcinoma of the head of the pancreas was indicated, but one could never be absolutely sure that there was no stone in the common duct. Even in the more serious condition considerable benefit followed anastomosis of the gall-bladder with the duodenum or stomach. Recurrent or persistent bleeding from the lower bowel without a sufficiently obvious cause necessitated exploration. Mr. Cope referred to a case which was at first thought to be one of haemorrhagic colitis, but later proved to have a papillomatous growth of the sigmoid. Mucous colitis had also been the first erroneous diagnosis in cases of renal tumour and cancer of the sigmoid. Increasing constipation in a patient whose bowel action had previously been regular was of great significance, even in the absence of other symptoms. If it persisted in spite of treatment, and the general health deteriorated, some stricture of the large bowel was probable. Alternate attacks of constipation and diarrhoea often indicated a growth of the colon. Vomiting could usually be diagnosed radiologically, but in one case of cancer of the upper jejunum, with copious vomiting, the radiogram showed no evidence of stricture. Conditions which sometimes gave no other indication than pain included: early gastric cancer; ulcer of the second part of the duodenum; cancer of the small intestine; tuberculous peritonitis and adenitis of the mesenteric glands; some cases of appendicitis, cancer of the colon, diverticulitis, cholecystitis, and gall-stones. With most organic abdominal conditions the pain was intermittent or periodic, and fairly constant in character. Tending to get worse in periodic attacks, it was associated with general constitutional depreciation, and might be accompanied by vomiting or sweating. In the early stages of the disease visceral pain was poorly localized unless the parietes had been reached. When a patient complained of pain which was constant in duration, had no definite relation to meals, was agonizing in intensity but unaccompanied by vomiting or sweating, and did not affect sleep, a mental origin should be suspected.

With the patient in the throes of an acute attack of abdominal pain there could be no waiting for an extensive series of investigations. By careful attention to minor points most of the causes could be diagnosed. In the more doubtful cases a consultation should be secured at once, so as to divide the responsibilty. Severe abdominal pain lasting more than six hours generally had a surgical significance. In every case the reflexes, pupils, urine, rectum, chest, and hernial openings should be carefully examined. If there was any likelihood of the condition being perforated ulcer, obstruction of the small intestine, appendicitis of the obstructive type, or a severe intraperitoneal haemorrhage from ectopic gestation, abdominal exploration was imperative. In frank peritonitis of doubtful origin it was generally wise to explore and drain, only dealing with the primary lesion if little manipulation was entailed. Cases of peritonitis seen in the late stages were sometimes better treated conservatively for a while, exploration being withheld until the patient's general condition had improved. Cases of severe distension without vomiting, due to dilatation of the large bowel, were sometimes puzzling, but there was usually time to give several enemata to diminish the distension, and so facilitate a more exact diagnosis. Cholecystitis and renal disease might closely simulate obstruction of the large bowel. In the absence of relief from enemata, exploration or a blind caecostomy would be necessary. In abdominal injuries few mistakes could result if exploration was performed in every case where severe pain lasted for several hours, and was accompanied by bilious vomiting, a rising pulse, persisting rigidity, or deep local tenderness with shallow respiration. A steadily rising pulse rate was in itself sufficient to call for exploration. Symptoms which might be due either to thoracic or abdominal disease presented a very difficult problem. If doubt existed after the most thorough clinical examination, a very limited exploration might be advisable. Every acute abdominal condition severe enough to simulate thoracic disease would give rise to an effusion into the peritoneal cavity of clear fluid, pus, or blood. If, under local anaesthesia, a one-inch incision was made into the abdomen, no harm was done to the patient, and the differential diagnosis could be made.

The Anglo-Yugoslav Children's Hospital, Belgrade, celebrates the tenth anniversary in its present building with the publication of a report on the varied and extensive work involved. During the period reviewed over 131,000 out-patients and nearly 7,000 in-patients have been treated. Serbian probationers and nurses have been trained, and the hospital has maintained its British characteristics, a matter of congratulation for the founder, Dr. Katherine Macphail.

Reports of Societies

NERVOUS DYSPEPSIA

At a meeting of the Section of Medicine of the Royal Society of Medicine on November 24th, with Dr. H MORLEY FLETCHER in the chair, a discussion on nervous dyspepsia was opened by Dr ROBERT HUTCHISON

Dr Robert Hutchison said that the expression "nervous dyspepsia" was a question-begging epithet He defined dyspepsia as discomfort during digestion which originated in the stomach, that excluded other intra abdominal conditions, even though the stomach functions were also disordered "Nervous dyspepsia" would exclude all organic disease, on the other hand, it should not be used as synonymous with all forms of functional disorder There were functional disorders due to other than nervous causes—for example, dietetic errors acting upon a stomach of low tone He suggested three groups of conditions which might be spoken of as nervous dyspepsia: (1) those of psycho-neurotic or central origin, due to mental disturbance or the anxiety state, (2) those due to fatigue, apart from mental perturbation, in this class the endocrine system played a part, but he thought the nervous system was also included, (3) the group in which no disorder of function in the stomach could be demonstrated, no loss of tone beyond what a great many people suffered without any trouble at all, those in which perhaps surgical exploration had been carried out without anything being found, and yet the patient habitually complained of symptoms referred to the stomach These might be spoken of as psychogenic, and might be due to a lowering of the threshold of consciousness They were cases very common in the visceroptotic type of woman There were two main groups of functional disorder the hyperasthenic and the asthenic Exaggerated nervous instability tended, through the vagus, to produce the first, fatigue and depressing emotions, the second He thought that every person had a tendency in one or other direction The hyperasthenic type was seen particularly in the sensitive "live wire" type of man, who threw a great deal of energy into everything he did, he tended to end up with duodenal ulcer Such a man, if overworked, might get an accentuation of his high tone and suffer from hyperasthenic dyspepsia On the other hand, in women who were subjected to depressing emotions, a lowering of tone below the normal expressed itself in the asthenic type of nervous dyspepsia Was there a disorder of sensory function? The gastric mucous membrane was normally insensitive, but possibly sensations not felt in health might reach consciousness in the psychogenic group, which comprised so many visceroptotic women It was only in that way that cases could be explained in which the patient complained of constant discomfort or even real pain, and for which the most careful exploration showed no cause The symptoms were rarely severe The presence of real as distinct from imagined pain might almost be said to negative a diagnosis of nervous dyspepsia The symptoms were usually discomfort, flatulence, and nausea, they varied from day to day, and were not much influenced by diet Diagnosis could only be made by exclusion, and must be based on a careful history and a thorough physical examination, supplemented by radiography and test meals if necessary Treatment should aim at removal of the cause. In the psychoneurotic cases this might involve the use of some form of psychotherapy to deal with the patient's anxiety state In the fatigue cases rest was the obvious procedure, rest in bed in the case of the more severe, and rest by way of a holiday in the case of the less severe Just at the present time there were a considerable number of nervous dyspeptics among business men who were worried by the financial situation In such cases symptomatic treatment might be required until the reason for the anxiety disappeared In the hyperasthenic type the treatment should consist of a bland diet, antacids, bromides, and belladonna, in the asthenic type, a dry diet, tonics, and physiotherapy But the real difficulty was the treatment of the psychogenic group, and he knew of no method which was uniformly successful or even reasonably satisfactory

Dr T A Ross said that more than half the patients whom he saw suffering from psychoneurosis also complained of dyspepsia A large number of the psychogenic patients had a fixed idea, which not only could not be removed by psychotherapy, but could not even be approached They would not even begin to discuss their complaint except from the premise that they had something which needed physical attention They were greatly helped for the time being by any form of treatment, provided it was sufficiently painful He had nothing to say which was helpful regarding these people They were very angry if it was suggested to them that their dyspepsia was of psychological origin He was not in complete agreement with Dr Hutchison on the question of fatigue For most people there was not only fatigue but a lowering of nervous energy, to use an electrical simile, amperage had been lost, and consequently there was a lowered potential, but it was equally possible that the full amperage or voltage was there, and the only thing that was wrong was that the patient for some reason or other would not use it Both exhaustion and dyspepsia might be effects of a common cause—namely, anxiety of some kind The treatment of this anxiety might be either radical or palliative It was well worth while to try palliative psychological treatment For most cases it must be the only thing one could do, because any analytical inquiry, at the shortest, meant three or four months with almost daily séances The palliative treatment should consist in discussing the current anxieties which the patient had, and in helping him to overcome them One of the most important of these anxieties was the question of diet The patient had made up his mind that this or that was an indigestible food, and if one could get him to see that practically all foods given in an ordinary household were digestible, he would find no difficulty in digesting them The speaker confessed that he was heretical enough to believe that all diet and drugs had their good effect through psychotherapy, and not through any chemical action they might possess A radical treatment would imply some form of analysis Occasionally one could not decide for many weeks what the patient's anxiety really was; the patient would deny anxiety for a long time, and then the truth would come out The aim of psychotherapy was not so much to relieve this or that symptom, but to get at the reason why the patient was anxious

Dr. H BEDINGFIELD said that nervous dyspepsia was to be regarded as an entity and to be differentiated from the physiological protective dyspepsia This condition had greatly increased since the war In women the symptoms began to get troublesome about the age of 18 to 20, and in men from 25 to 30 They were more common in married men than single, and in single women than married Pain tended to be localized most frequently in the upper abdomen Nearly all the cases fell into two groups those with intermittent symptoms, alternating with long periods of good health, and those in which the symptoms tended to persist, fluctuating in intensity and accompanied by signs and symptoms of nervous and emotional instability Physical examination revealed nothing to account for the symptoms From the physician's point of view, the chief interest of these cases was the explanation of them Although the symptoms appeared comparatively late in

life, in every case that he had investigated so far there had been a history of digestive disturbance of some kind in early infancy. Health might be defined as an adjustment between the individual and the environment. This integration might be upset by inherited, congenital, or acquired defects, and it was legitimate to look to the cortical personality for an explanation. At the dawn of mental life there already existed a mature, ready-made, psycho-physiological mechanism to reflect any disturbance in development. Such disturbance might be brought about by unsuitable alimentation, by some congenital or inherited defect in the primordial protoplasm, or by lack of harmony in the development of cortical personality. This last depended largely on the emotional influences which played around the child. Any disharmony would be reflected physiologically in the gastro-intestinal tract, as being the only site of physiological mechanism available, and later maladjustments would tend to use the same path. Dr. Bedingfield discussed the psychological factors involved, pointing out that severe and prolonged disturbance would lower the threshold until sections of the gastro-intestinal tract rose up into consciousness in the form of pain and discomfort. With regard to the treatment of these individuals, analysis was the only possible method of relief. There was no question that the severe cases were psychotic in nature, but, as Dr. Ross had said, utterly unapproachable.

Dr. J. A. RYLE wished to add to Dr. Hutchison's list dyspepsia due to nervous tricks, such as air swallowing. There were cases of dyspepsia in which air swallowing was the main cause, and others in which it was subsidiary. This trick sometimes started with a simple naso-pharyngitis, and he had seen it started after an anaesthetic, but most of all it was a symptom of an anxious mind. The woman suffering from chronic anxiety practically always had this symptom, sometimes in extreme form, and the important thing was the ease with which it could be recognized clinically. One had only to ascertain from her that it was a form of flatulence and eructation which continued. It was an important symptom to treat, and, when removed, a large part of the dyspepsia, sometimes the whole of it, could be cured. In the mistreatment of anxiety dyspeptics the chief trouble was diet. If one could get it out of their heads that dyspepsias were due to food it would be a good thing. It was only in the minority of cases that it was due to food, but often, he with the advised patients, one article of diet after another was a one-inch incision, consequent loss of weight, so that a those of serious physiology beginning a spare person ended, be due to organic disease and thin, or even emaciated. It Jaundice, persisting for some who was to blame for this exploration if no tumour could be ably a doctor, or various gram provided negative evidence of gen too often cut out If persistent and painlessly increasing, With the female head of the pancreas was indicated, but ing to be under be absolutely sure that there was no stone was encouraged duct. Even in the more serious condition benefit followed anastomosis of the gall-bladder ed what Dr. duodenum or stomach. Recurrent or persistent ation that from the lower bowel without a sufficiently obvious d until necessitated exploration. Mr. Cope referred to only be which was at first thought to be one of character of the colitis, but later proved to have a papillon One patient said of the sigmoid. Mucous colitis had also "Doctor, aren't erroneous diagnosis in cases of renal tumour en tomatoes?" of the sigmoid. Alternate attacks of constipation extreme imrhoea often indicated a growth of the colon.

portance for the maintenance of health and the attainment of longevity. To explain what he meant by this class of normal nervous reactions, he would take the case of a physician who, after a strenuous morning's work, unwisely tried to take an ordinary midday meal with his family, but in half the time taken by the other members of the family, before leaving to keep an important early afternoon engagement. He vomited while in his car on the way to his engagement. In his temporary state of mental strain he clearly ought not to have taken an ordinary meal. Those who, in such circumstances, could eat a fairly full meal with apparent benefit were those bodily and mentally robust individuals who, if they habitually did that kind of thing, paid the penalty by unnecessary degenerative disease, and died at 60, whereas those who were "hampered" by the nervous reactions in question, which were really protective in nature, were more likely to remain healthy and live to 90.

Dr. BLACKBURN, as a general practitioner, gave his experience that the commonest condition found in nervous dyspepsia in children was an intolerance of fats; he had found the same thing in adults. Dr. STOLKIND related some cases from his experience illustrating the influence of mind on gastric function, and Dr. MIRVISH said that he thought it was important to consider how far a case was really functional, and how far there was possibly an organic basis.

Dr. HUTCHISON, in reply, said that there had been more agreement shown in the discussion than might have been anticipated. It was a sincere relief to him that these troublesome cases of "abdominal women," in which the physician could find nothing, were really psychotic. With regard to air swallowing, he was always teaching his students that aerophagy was not dyspepsia at all; it was nervous, but it appertained to the oesophagus, not to the stomach. He agreed that there was over-dieting of the nervous dyspeptic, but one must not go too far in the other direction. There were certain common-sense simple rules which it was worth while to impress upon these patients, though finicky menu-writing was quite unnecessary.

ACTIVE IMMUNIZATION IN VIRUS DISEASES

At a meeting of the Section of Comparative Medicine of the Royal Society of Medicine on November 25th, with Dr. J. A. ARKWRIGHT in the chair, a discussion on active immunization in virus diseases was opened by Dr. C. H. ANDREWES.

In attempting active immunization against a virus disease, Dr. Andrewes said, the ideal should be to produce an immunity at least as good as that which follows the naturally contracted disease, an immunity dramatic as regards solidity and duration. At present this ideal seemed to be attainable only by producing a mild attack of the disease. The use of killed or apparently killed virus only conferred immunity of a much lower order than this. Some observers believed that the production of such immunity depended on the persistence of the virus in the animal body, although there was no evidence either in favour of or against this view. Those who believed it could conclude that the living virus was essential to the production of immunity of a high order. A mild attack of the disease might be produced by the inoculation of attenuated virus; sometimes a suitable virus was found ready made, like vaccinia, and sometimes the attenuated virus could be obtained in a stable form by passage through a series of animals—for example, rabies fixed virus. More often it was necessary to produce a mild attack of disease by inoculating fully virulent virus into a partially immune animal. The partial immunity might

be achieved actively by means of formalinized, apparently killed, virus, or passively by means of inoculations of virus and serum into opposite sides of the body (side-to-side method). In a few cases—for example, yellow fever—serum-virus mixtures could be made outside the body and injected at one site. In those cases in which this method failed it was probable that the antibody of the serum acted rapidly on the virus before injection. The mechanism by which these methods produced an attenuated disease was obscure. The virulent virus was believed to multiply in the body, but not quickly enough to overcome the partial immunity induced. It was found that the active immunity produced in rabbits by the side-to-side inoculation of neuro-vaccinia and anti-vaccinal serum was developed very rapidly, within twenty-four hours. There was a danger that the production of immunity, by giving a mild disease, might lead to the spread of disease; animals reacting abnormally to vaccination might infect others. Waldmann, Trautwein, and Pyl had reported that cattle hyper-immunized against foot-and-mouth disease might excrete virus in their urine as long as 246 days after inoculation. Studies on similar lines were needed in other virus diseases.

Professor W. J. TULLOCH gave a brief summary of his work, and that of Dr. James Craigie, on vaccinia. The diagnostic value of the vaccinia flocculation test and its specificity, he said, appeared to be proved, but his findings had been discussed in a recent publication; he therefore proposed to deal with further investigations which broke new ground. It was possible to separate extracts of vaccinia material into two moieties, one of which was markedly flocculable and of low infectivity, while the other was not readily flocculable, but was highly infective. The separation could be achieved by filtering suitably prepared extracts of the material through a Seitz E. K. disk, and then—the disk having been washed to remove any flocculable substance contained within it—by reversing the disk, washing in the reverse direction; the filtrate was flocculable but not infective, and the material obtained by the reverse process was infective but not markedly flocculable. Flocculable substance might be the product of the living virus, a product of the dead virus, a product of the invaded tissue, or a combination of these. Possibly its relation to the virus might be akin to the relation between pneumococci and their specific carbohydrates. He had found that flocculable substance inoculated into normal rabbits failed to stimulate the production of flocculating antibody, but inoculated into rabbits previously vaccinated by dermal vaccination alone it gave rise to a marked development of flocculating antibody. The suggestion that the filtrate contained living virus in quantities sufficient to act as a secondary stimulus, but insufficient to act as a primary stimulus, seemed unlikely in view of the large doses used. Two points emerged from the experiment: first, that a material which failed to act as a primary stimulus might act as a secondary stimulus to the production of antibodies; and secondly, that there was so close an association between flocculable substance and virus that it looked as though flocculable substance was the product of the virus, living or dead. Dr. Craigie had recently shown that flocculable filtrates, proved by testicular inoculation to be free from virus, led to an early and severe response when inoculated into humans who had already been immunized by ordinary vaccination.

Major DUNKIN said that in dog distemper the dog which had recovered from a natural attack usually enjoyed life-long immunity, but there were a few exceptions in which a second or third attack had been said to occur. These, however, might be bacterial infections, with symptoms resembling virus distemper. Immunity to distemper might be established in dogs and ferrets by the use of formalinized virus. Single doses did not confer lasting immunity, but two doses injected at intervals of a week or a fortnight produced an immunity of longer duration. Vaccine followed by living virus produced an active and durable immunity. The method of side-to-side injection of serum and virus was promising, but needed longer study. The injection of mixtures of serum and virus gave disappointing results. Virus undergoing degradation from storage in a moist condition reached a stage at which it would fail to reproduce the disease, but acted as an efficient antigen. Subinfective doses of living and virulent virus did not appear to produce immunity. It was possible that an immunized animal became a perpetual carrier of the disease, though attempts to recover the virus from such animals had failed.

Dr. S. P. BEDSON said that the ideal to be aimed at was the maximum of immunity with the minimum of danger and discomfort. He described some observations on psittacosis virus in which he had found that the immunity conferred by an attack was mild; he had also found that the guinea-pig was insusceptible to the disease, but its serum had little immunizing power. It was often said that a "killed" virus was not really killed, but only apparently dead. He had experimented with herpes virus, and had found that formalinized virus produced better immunity than virus which had been steamed for twenty minutes, or than formalized virus which had been steamed for the same period of time.

Mr. R. E. GLOVER said that so far as animals were concerned the serum and virus methods appeared to give the best results. The difficulties lay in maintaining and distributing a potent strain of virus, and in the danger of infection. In his opinion it was better to run the risk of infection than to use a method which gave only a fleeting immunity. He had carried out experiments with a strain of pigeon-pox of low virulence, from which the severity of the lesions produced by high dilutions had been approximately equal to that produced by low dilutions. Single doses had been found to give a partial immunity of short duration, while two doses gave almost complete immunity, declining after four weeks. By allowing formalin to act on the virus for varying periods of time it was found that a point was reached at which the quantity of living virus was insufficient to set up the disease, but an adequate amount remained to provoke an immunity response; at a further stage the virus was destroyed and became antigenetically inert. He described some experiments designed to procure immunity by the use of vaccines made from virus cultured *in vitro*; pigeons receiving culture vaccine had shown only a trace of immunity.

Dr. M. H. GORDON thought that modern investigations tended to show that virus was composed of very small organisms. Vaccinia virus was apparently held up by an ordinary filter. Did these organisms produce their effects by means of toxins or endotoxins? If some clear conception of the nature of vaccinia virus could be obtained better success might be hoped for in dealing with the obscurer types.

Professor J. C. G. LEDINGHAM believed that the ideal was to produce what immunity was possible by the use of killed virus. It was quite justifiable to use living virus to immunize animals, but with men he thought only killed virus should be used. Major T. DALLING said that quite a high degree of immunity to canine distemper could be procured by the use of even one dose of attenuated or killed virus, and even more by two doses. Although this appeared to have considerable duration in the laboratory, in the field results were more doubtful. Mixtures of serum and vaccine were ineffective in producing immunity

to dog distemper. Dr. WILSON SMITH, working with neuro-vaccine, had found that upon boiling an extract made from inoculated testis for fifteen minutes, no protein reaction was obtained, but there was a precipitin reaction with vaccinia serum, possibly of a carbohydrate nature; the extract would not, however, produce immunity in rabbits.

Professor G. H. WOOLDRIDGE asked how long infectivity might remain after vaccination—for example, with dog distemper. An infective dog might be dangerous if admitted to a veterinary hospital where the patients were temporarily out of reach of the general infection of the street. It had been found in America that animals recovering from swine fever often remained carriers. Was it likely that dogs vaccinated against distemper became carriers? Dr. R. A. O'BRIEN said that it was not easy to say. He had placed recently immunized pups with pups known to be susceptible to distemper, and it was only possible to say that he had never had any proof that the immunized pups were infective to others. Captain S. R. DOUGLAS agreed that he had never had a case of an immunized dog infecting other dogs, but quoted a doubtful case in which an immunized ferret had been suspected of carrying infection. In controlled experiments where the disease was mild, dogs did not appear to be infective, even where there was a definite reaction. With a severe reaction—that was where immunization had failed—the dog was able to pass on the disease. Dr. J. T. EDWARDS said that no infection took place between healthy cattle and cattle immunized against (?) rinderpest. He had immunized 20,000 cattle in Mysore, with the extremely low mortality of 0.6 per cent. Rinderpest did not break out in any of the villages to which the cattle were sent. Such a mortality, though admirable in cattle, would not be tolerated among human patients.

The PRESIDENT said that he was interested to hear that dead vaccines were beginning to look up. He thought it might be worth trying the effect of large quantities of dead vaccines, perhaps given in several different places in the body. The observation that vaccinia virus might be split into two parts, one of which was possibly of a carbohydrate nature, seemed to him to be particularly interesting.

LIVER FUNCTION TESTS

At a meeting of the Medical Society of London, held on November 24th, with the president, Mr. HERBERT TILLEY, in the chair, a discussion took place on the methods of determining liver function and their value.

Sir HUMPHRY ROLLESTON, opening the discussion, first outlined the difficulties of applying functional tests to the liver. The liver, he said, had many functions, and in order to investigate their efficiency corresponding tests had been employed in such profusion that it was impossible to enumerate them. The tests for any one function, though giving that particular information, could not be expected to throw light on the other functional activities of the organ. For example, one of the functions which concerned the liver, but for which it was not exclusively responsible, was the excretion of bile. This might fail, while the glycogenic function might appear to be competent. If there were any evidence that the hepatic functions broke down in a constant sequence, tests for the last function to be disordered would throw light on the condition of the liver as a whole; but, unfortunately, no such sequence was known, and the hoped-for single and comprehensive test for total hepatic efficiency was not available. Sir Humphry next dealt with determination of the total, or so-called "global," functional capacity of the liver in removing dyes from the blood after intravenous injection. He pointed out that, while tests involving the use of phenoltetrachlorphthalein or bromsulphalein have led to the adoption of cholecystography, other investigations with these dyes have been largely abandoned. Many of the functions of the liver were shared in some degree with other organs or tissues of the body, so that tests such as the levulose tolerance test gave information as to the carbohydrate metabolism of the body as a whole, and not of the liver alone. A further difficulty was the great reserve power of the liver. In animals four-fifths of the organ could be removed experimentally without bad effects, while, after damage to the liver, compensatory regeneration rapidly took place, with restoration of functional efficiency. Hence, the speaker continued, it was in acute rather than in chronic lesions of the liver that functional tests were likely to give constant evidence of impaired activity. In acute yellow atrophy the clinical picture usually gave sufficient data for the diagnosis, and the need for further tests might not arise. In the treatment of syphilis by arsenobenzol preparations, evidence of impaired function in the excretion of bile was valuable, as it gave a warning of liver changes and an indication for the cessation of the injections and the administration of glucose. For such a condition Sir Humphry recommended examination for bile acids in the urine (Hay's test), "latent" jaundice being determined by the van den Bergh test. Both methods were simple and rapidly carried out in routine work. In cases of chronic ascites not due to hepatic disease negative results with the Bengal rose test (Barker's) might be useful in diagnosis, but in ordinary portal cirrhosis the functional tests frequently failed to give any help. The value of van den Bergh's reaction in the diagnosis of different forms of jaundice was an established fact, but in the levulose and galactose tolerance tests results might frequently be vitiated by the compensatory power of the liver.

Professor E. C. DODDS said that ten years ago there had been a similar discussion held on this subject, and there was probably little fresh to be added to-day. A study of the literature showed that up to 1920 tests for hepatic function abounded, but in 1921 a change took place, leading gradually to the abandonment of one test after another. This change could be traced to publications of F. C. Mann and others at the Mayo Clinic. Professor Dodds then gave, in some detail, the results of Mann's experiments in removing the liver from animals. The animal quickly recovered from the operation, and for an hour afterwards appeared quite normal. It might remain so for three to eight hours. The following symptoms then developed: muscular weakness, loss of reflexes, complete flaccidity, twitchings, convulsions, and subsequently death, preceded by vomiting. These results, very similar to those of hypoglycaemia produced by overdosage of insulin, represented a grave disturbance of carbohydrate metabolism. Of other supposed functions of the liver there was often very little evidence of upset. Uric acid in the blood was increased, but there was no rise in urea. Jaundice developed about six hours after complete removal of the liver, and the van den Bergh reaction gave an indirect or delayed-direct result. There was no evidence of lack of conjugation of phenol and salicylic acid, and, when these were given to hepatectomized animals, glycuronic acid derivatives appeared in the urine. The plasma proteins remained unchanged, and no alteration could be detected in the haemoglobin or red cell content of the blood. Further experiments, in which Mann removed up to 80 per cent. of liver tissue, showed practically no alteration in the animal when the usual tests were applied. Hence, the chances of using such tests for detecting early stages of liver disorders were small. From

a practical point of view, however, Professor Dodds had personal experience of, and faith in, the galactose tolerance test and the estimation of bile pigments in the blood For example, in a patient of 40, a marked rise in blood sugar after the administration of galactose would favour a hepatitis rather than an obstructive cause for jaundice, and this test would be helpful in prognosis. The van den Bergh method of estimating bile pigments in the blood was valuable, as was the simple clinical method of determining the icteric index In conclusion, Professor Dodds urged the wisdom of accepting Mann's work and dropping all other tests as valueless.

Dr W LANGDON BROWN said that since the discussion of ten years ago the lipase test and the haemoclasic crisis of Widal had been proved of no value, while galactose had replaced levulose for the sugar tolerance test of liver function Since that discussion the introduction of cholecystography had occurred, and also the discovery of insulin, which had led to a better understanding of the symptoms of complete hepatic breakdown He thought the old clinical observation that the antitoxic power of the liver demanded an adequate store of glycogen had been to some extent confirmed, and in this connexion he referred to the importance of giving glucose in cases of cholaemia

Dr A F HURST emphasized that the early stages of liver disease could be, in his opinion, detected by the levulose tolerance test. He thought it possible by this test to recognize the earliest stages of alcoholic poisoning of the liver, a disorder which was becoming more frequent as alcoholic cirrhosis became less. He took as a positive result for this test a rise of over 20 mg. per cent. in the blood sugar in one hour, and a failure to fall to the fasting level in two hours In people who came home from the Tropics and complained of feeling "liverish" the test had given evidence of hepatic insufficiency. After treatment by emetine the test became normal, suggesting that an amoebic hepatitis had been present In gall-bladder disease he had found evidence of an associated hepatitis by this test, and it was important to treat this liver disorder both before and after operation In a fourth group of people who complained of feeling "liverish" evidence of hepatic insufficiency by the test had been present in nine out of ten cases Such patients were benefited by treatment Lastly, Dr Hurst mentioned catarrhal jaundice He believed that there were two types with the same clinical picture one was a true hepatitis, and the other a true obstruction due to gastro-duodenal catarrh The levulose test differentiated between the two

Dr J W MCNEE said that the earlier workers on liver disorders were ignorant of those modern methods of estimating the blood sugar which had done so much to explain symptoms of hepatic insufficiency He had gradually discarded most of the tests for liver function. While the van den Bergh reaction was often disappointing in differentiating clinical varieties of jaundice, it had been of great value in the theoretical unravelling of the problems of this disorder He had not had the same success as Dr Hurst with the levulose tolerance test, and felt that it gave little more information in diseased conditions than could be obtained clinically. The real difficulty was to know the margin in chronic cases between hepatic efficiency and complete insufficiency. The latter was coincident with death in many instances, and a test or this margin of safety did not exist. He thought that reat care should be taken in applying all Mann's animal xperimental work to the human subject

Dr G E BEAUMONT hoped that the realization of odern ignorance on the subject of reliable liver function ts would be widely disseminated among the profession He asked if a localized area of hepatitis adjacent to a diseased gall-bladder could possibly give rise to alterations in the levulose tolerance test. Dr. N. H FAIRLEY pointed out that the bromsulphalein test was still being used at the Mayo Clinic, while the levulose tolerance test had been abandoned In amoebic hepatitis he had been disappointed in the use of this test. Sir LEONARD ROGERS described the use of tests to prove absence of gross disorder of liver function in cases of amoebic abscess treated by simple drainage. They had proved that death from the bigger surgical procedures was due to septicaemia rather than to hepatic failure Dr A CRAWFORD pleaded that the problem was essentially a clinical one, and that all liver function tests ought to be interpreted clinically. There were various tests that could be of use, apart from those accepted by the biochemists The condition of the proteins in the blood, the investigation of sulphur metabolism, and Widal's haemoclasis reaction could all give help if interpreted by the physician Sir WILLIAM WILLCOX said that what clinicians wanted to know was the condition of the liver cells, not as regards jaundice, but as to the general condition of health of these cells. He thought that complete hepatic insufficiency could not be altogether explained by invoking the theory of hypoglycaemia, at any rate as far as human subjects were concerned Death in such cases as icterus gravis was probably caused by some autotoxin in the blood. Attention should be directed towards a delicate test for the presence of this body, which was probably a decomposition product

---

At the inaugural meeting of the new session, Mr C. Schelling, retiring president of the Section of Odontology of the Royal Society of Medicine, presented to the Section and endued his successor, Mr E B Dowsett, with a badge in gold and enamels for the use of successive presidents of the Section The design, executed by Mr Harold Stabler, is surrounded by a wreath of laurel leaves in green enamel, and displays in the centre the shield taken from the large badge presented to the Royal Society of Medicine by Sir StClair Thomson It is enamelled in the proper colours, and bears the Tau Cross of Moses with the Serpent in gold entwined, and above that a gold portrait medallion of John Hunter copied from the die which was in use by the Odontological Society prior to its amalgamation with the other societies now constituting the Royal Society of Medicine Inserted in the case is a suitable dedication

---

At the half-yearly council meeting of the British Red Cross Society, held in London last week, with the Duke of York in the chair, the annual report was received Satisfaction was expressed at the increase in activities, particularly the enormous strides made in the development of the blood transfusion service There were now 1,800 donors on the books, and, judging by the present rate of progress, the number would be over 2,000 by the end of the year. As many as eighteen calls for blood transfusion had been received in one day The report of the Red Cross Clinic for Rheumatism showed that over 2,000 patients a week were now being treated at the clinic To deal with the increasing numbers consultation clinics had been increased to twelve per week For the convenience of patients at work during the day, several of these were held in the evenings One gratifying feature was that while a number of cases of advanced rheumatism still came in for treatment, the number of early cases was steadily increasing There was now no waiting list either for men or for women

Reviews

RHEUMATIC INFECTION IN CHILDHOOD

Among the various monographs that have been devoted to the important subject of acute rheumatism during the past fifty years, we do not recall one that has approached it from quite the same point of view as that which Dr. LEONARD FINDLAY[1] has chosen. It is therefore all the more fortunate that the task has been undertaken by a physician whose long and wide experience of disease in children has included a close attention to that which he calls "the rheumatic infection in childhood"—the same group of phenomena that has been more briefly designated "juvenile rheumatism" by Dr. Reginald Miller. The author's interest in the subject has been predominantly clinical, and for this reason—doubtless also because of limitations of space—the bacteriological and histological aspects of the disease are scarcely discussed. This is, however, hardly a fault, since it affords the author a better opportunity for expounding his clinical conclusions. These are based on an analysis of over seven hundred cases seen by him at the Royal Hospital for Sick Children, Glasgow, more than half of which have been under his observation for more than five years.

After an introductory chapter, which reviews the history of the subject, there is an interesting summary of the data collected in various localities which bear on the question of incidence. From these Dr. Findlay states that "whatever the conclusions to be drawn from the figures relative to England and Wales, there is absolutely no evidence that in the West of Scotland rheumatic fever and chorea are becoming any less prevalent." His view of the connexion between the rheumatic infection and defective housing conditions is more in accord with the current teaching, and he is also in agreement with other observers in believing that rheumatic manifestations following scarlet fever are for the most part examples of true rheumatic infection. In the chapters which follow, the clinical data which he has amassed are subjected to a close analysis, and if this is at times rather cramped by the statistical method adopted throughout, many observations emerge which otherwise might have remained obscure. There are, for example, numerous facts which bring out, on the one hand, the close relation between chorea and other rheumatic lesions, while demonstrating, on the other hand, the fact that, of all the principal manifestations of rheumatism in childhood, chorea is the one which is most likely to occur without either of the others. There is an admirable survey of the role of rheumatism as a cause of organic heart disease in childhood. His figures show that of 489 cases of non-suppurative endocarditis in childhood, no fewer than 473, or 96.7 per cent., were probably rheumatic in origin. In his survey of the cause of the disease he has supplemented his own figures by adding to them a series drawn from the Western Infirmary, Glasgow, and has thus been able to show that there are two peaks of increased mortality caused by the disease—the one during later childhood (10 to 15 years of age), and the other during the age period 35 to 45 years. He concludes that

"Of those infected during childhood about one-third escape involvement of the heart—this proportion probably will be slightly less in the case of arthritis and slightly greater in the case of chorea. By about ten years after the onset of the infection distinctly more than a third of the patients will have died from the severity of the cardiac implication. One-third of the cases will be more or less incapacitated—it is these cases which accumulate as the older ages of the population are reached, and which, with the onset of arterio-sclerosis, swell the death rate from rheumatic cardiac disease."

Dr. Findlay is a firm believer in prolonged rest as an essential basis of treatment of the rheumatic infection. His general rule is to keep children with chorea or arthritis in bed for three months as a means of preventing or limiting the cardiac injuries. He uses salicylate freely, not only for the arthritis, but also in the treatment of chorea. Here, it is to be noted, he has little faith in the value of arsenic. His experiences do not encourage him to expect much from tonsillectomy as a means of cutting short the infection. Finally, he advocates strongly the development of the "heart hospital" experiment, though he thinks it too soon to attempt an assessment of its value. To everyone who is impressed both by the prevalence and by the pertinacity of this infection, Dr. Findlay's book will be not only a mine of information, but also an encouragement in the pursuit of thorough-observation and prolonged treatment.

DETACHMENT OF THE RETINA

Up to the past year or so retinal detachment has proved a condition in which the surgeon could offer little or no hope of successful treatment, and owing to the gravity of its effects, which almost invariably result in the eventual loss of vision, it has proved to be one of the most dreaded diseases to which man is heir. The number and variety of the methods of treatment which have been proposed from time to time, the short duration of their popularity, and their rapid disappearance from the field of therapeutics, provide ample evidence of their practical inefficiency, and the customary policy which has been adopted of maintaining enforced and absolute rest for a long period, with usually negative results, speaks for itself. During the past year or two, however, the new method of treatment by ignipuncture, suggested and ably practised by Professor Jules Gonin of Lausanne, has to a very large extent altered the outlook in those cases, and has introduced an element of hope into the prognosis of the condition. The technique of the operation itself, its indications and contraindications, and the proportion of successful results which may be anticipated from it, are now widely known; and, although the origin of the new method of treatment was almost entirely empirical, its success has had the further value of stimulating a great deal of fresh investigation into the etiology and pathology of retinal detachments. The literature of the subject is already vast and scattered, and, as can well be imagined, is extremely incoherent and indeterminate. For this reason, now that a definite milestone has been reached and a new start, as it were, is being made, a critical summary of what has been done before is of more than ordinary interest. In his monograph on *Detachment of the Retina*[2] Mr. RINGLAND ANDERSON has accomplished this difficult and laborious task in an excellent manner, and has put into its true perspective all that is of value in the knowledge which has so far accumulated. As a starting point for further and more successfully directed investigations his work is of much importance.

After a survey of the general incidence and diagnosis of detachment of the retina, the author deals in considerable detail with the anatomy and physiology of the tissues which are involved. The pathogenesis of any condition must obviously be based upon physiological principles. Hitherto, the cause of a simple detachment has remained unknown, largely because the physiology of the eye and of the intra-ocular pressure is also unknown, and until the latter subject is much more fully elucidated it

[1] *The Rheumatic Infection in Childhood.* By Leonard Findlay, M.D., D.Sc., M.R.C.P. London: E. Arnold and Co. 1931. (Pp. vii + 187; 10 figures, 19 charts. 10s. 6d. net.)

[2] *Detachment of the Retina.* By J. Ringland Anderson, M.B., B.S., F.R.C.S.Ed., etc. With a foreword by Sir Herbert Parsons, C.B.E., D.Sc., F.R.C.S., F.R.S. London: [illegible] bridge University Press, 1931. (Pp. xiv + 207; 7 plates [illegible] net.)

is impossible even to commence the study of the former on sound lines with any hope of success. Much progress has been made in the past few years in our knowledge of the physiology of the eye, but until much more is done the cause of derangements in function must remain speculative. The author concludes that among the cases of idiopathic detachment there are two main groups: one is essentially due to degeneration, whether it be in the form of cystoid changes in the retina, liquefaction of the vitreous body, or alterations in both of these tissues after chorio-retinitis; the other is due to chorioidal effusion. In the first group the appearance of a retinal tear is an essential feature, in the second it is incidental. The prognosis in the second group of cases is better than in the first; the outlook in traumatic cases, if operative treatment is undertaken, is generally (relatively) favourable; and the prognosis in myopia, owing to the associated degeneration, is worse than in emmetropia and hypermetropia. The author stresses one important point, too often forgotten—namely, that apart from those cases due directly to trauma, the majority of detachments are secondary to some uveal disease. A lesion of this nature may lead directly to a subretinal effusion and a consequent detachment, or indirectly, by producing degeneration in the vitreous, retina, or ciliary body, may involve a predisposition to detachment. In these circumstances a very slight trauma, or a transient vascular derangement, may be sufficient to precipitate the detachment, whether it be by means of a retinal tear or a chorioidal effusion. Because of the fundamental part played by uveal disease it is necessary to go a step beyond the local ocular condition, for in the great majority of cases uveal disease is due to some general morbid condition. For this reason, apart from local conditions in the eye, much of the pathogenesis of retinal detachment will remain unsolved so long as work in the field of general pathology is obscure; and for the same reason the treatment of the condition should not be limited to the mechanical repair of the local damage, but should include an attempt to elucidate and eliminate the ultimate cause.

The volume, which is published under the auspices of the *British Journal of Ophthalmology*, forms a worthy addition to the series of monographs sponsored by that journal; and the illustrations are of the high order we are accustomed to expect from the Cambridge University Press.

HIGH BLOOD PRESSURE AND RENAL DISEASE

In his large volume on *Hypertension and Nephritis*[2] Dr. ARTHUR M. FISHBERG, who is attached to the Mount Sinai and to the Beth Israel Hospitals of New York, reviews in considerable detail a wide field. The first five chapters, or a quarter of the volume, deal with preliminary though useful subjects—the pathological physiology of renal function, tests of renal efficiency, albuminuria and casts, oedema, and uraemia. This, the second, edition has been thoroughly revised, is fifty pages longer, and its value as a source of reference is greatly increased by the bibliographies appended to the various chapters. That the author has scrupulously kept the text up to date is shown by the additions he has made; for example, in the section on the pathogenesis of arterial hypertension, a clear description is given of Hering's recent investigation on the carotid sinus and its relation to blood pressure. Pressure on the bifurcation of the common carotid (the carotid sinus), long known to cause slowing of the pulse and formerly ascribed to mechanical stimulation of the vagus, is now thought to cause reflex fall of blood pressure and slowing of the heart through the sensory nerves on the carotid sinus, which were formerly called "depressor" and now the "blood pressure restrainers." Section of these nerves causes hypertension, but there is no reason to regard the mechanism of human hypertension as analogous to this experimental form. In a short, but good, discussion on the point, Dr. Fishberg concludes that, in spite of opinions to the contrary, it is improbable, and has not been proved, that syphilis is a cause of high blood pressure. After discussing the perennial problem of the classification of renal disease, he adopts one based on that of Volhard and Fahr. Four forms of nephrosis, the term introduced by F. Müller in 1905, are described: the larval, occurring in the course of fevers, the necrotizing, the chronic, and the amyloid.

Dr. VITAL LASSANCE of Bains-les-Bains divides his remarks on Raised Arterial Blood Pressure[4] into five parts, dealing in turn with its causation, clinical aspects, methods of examination, prognosis, and treatment. Thus he covers a wide field. He describes different sphygmometric types, such as a raised systolic pressure only and a raised diastolic pressure only, which are spoken of as false hypertensive conditions, and true hypertension, in which both the systolic and diastolic pressures are raised, there being subdivisions in the cases with a satisfactory circulatory equilibrium, those with a predominant rise of the systolic pressure, and those with a predominant elevation of the diastolic pressure, as in cardiac failure. High blood pressure after 60 years of age is less likely to progress, and is of better prognosis than at a comparatively early age. There are seven pages of bibliography, all from French-speaking authors.

LECTURES ON PHARMACOLOGY

The *Lane Lectures on Pharmacology*,[5] delivered by Professor W. STRAUB of Munich in 1929, have just been published by the Stanford University Press. Two of the lectures are devoted to the chemistry and biochemistry of digitalis, a subject that the researches of Professor Straub and his pupils have done much to elucidate. The other four lectures deal with pharmacological subjects of special therapeutic interest—namely, drugs of addiction, basal anaesthetics, organic compounds of the heavy metals used as disinfectants, and camphor and the modern analeptics.

The lectures on digitalis are of particular interest, because they summarize in an authoritative manner a large amount of important recent research. The chemistry of the digitalis glucosides has long been notorious for its difficulty and complexity. The chief glucosides have at length been identified with some certainty, and a start has been made on the task of elucidating their structural formula. Knowledge regarding the fate of these glucosides in the body is, however, relatively advanced, for reliable estimates are available for the amounts fixed by the frog and mammalian heart; moreover, estimates have been made both of the rate at which the drugs are fixed and also of the time taken for their action to pass off from the heart. These results show that digitalis glucosides which reach the heart are fixed rapidly, but that their action persists for a remarkably long period, for the effects on the heart of a single intravenous dose still persist after a fortnight.

[2] *Hypertension and Nephritis.* By Arthur M. Fishberg, M.D. Second edition, thoroughly revised and enlarged. London: Baillière, Tindall and Cox. 1931. (Pp. xvi + 619; 1 coloured plate, 38 engravings. 30s. net.)

[4] *Hypertension artérielle.* Par Dr. V. Lassance. Paris: N. Maloine. 1931. (Pp. 310. 19 figures. 35 fr.)

[5] *Lane Lectures on Pharmacology.* By Walther Straub, M.D., Ph.D. Stanford University, California: Stanford University Press; London: Milford, Oxford University Press. 1931. (Pp. 87; 2 figures. Paper, bound, 1·50 dollars.)

The lecture on intoxicating drugs is extremely interesting, and the lecturer even had the courage to present to California the ideas of Munich on alcohol.

"A certain standard of civilization, a temperate climate, and an organization of life based on a systematic arrangement of work . . . are essential conditions for the enjoyment of alcohol. With the individual, however, these conditions are not absolute; they are modified by that moral standard which is called moderation. For thousands of years, millions of people have voted for alcohol. Meanwhile, science has motivated the instinct which led Noah to his famous discovery."

The other lectures provide a lucid explanation of the outstanding problems in the subjects with which they deal. All the lectures are characterized by a clear and stimulating manner of presentation, a fact that will cause no surprise to those who are aware of Professor Straub's renown as a scientific lecturer.

OTO-RHINO-LARYNGOLOGY

The collection of Précis of Masson is famous, the best known in this country being perhaps the *Précis de Dermatologie* by Darier. Dr. GEORGES LAURENS, with his collaborators AUBRY and LEMARIEY, has added another volume, *Précis d'Oto-Rhino-Laryngologie*,[6] which well maintains the exacting standard. The information supplied lacks nothing in detail and in accuracy, and the even flow makes the book most pleasant to read. A striking feature is the perfect balance which is maintained between the many different sections, no part being dismissed too lightly, while no unnecessary stress is laid upon any other. The wide knowledge, long experience, and deep reading of the principal author is revealed in this achievement. He himself modestly claims that, as no originality is required, he has done his best to make the *Précis* clear and practical. He has succeeded admirably and at the same time has made a notable addition to the literature of oto-laryngology, something far beyond the mere compilation which the bare title implies. The precision and clarity with which the subject is exposed is displayed nowhere more clearly than in the section on the ear. The complications of otitis media and the pathological conditions which affect the labyrinth, subjects which must tax the powers of any writer, are described so fully and yet so simply that it is hardly possible to imagine anything better in this style. A search for instruction on any point provides clear and full teaching, so that the book appears to be complete in every direction, and it is sufficiently but not lavishly illustrated. It is so well adapted to its purpose of a textbook for the practitioner and the student of oto-laryngology that it deserves to circulate far beyond the limits of the country which gave it birth.

NOTES ON BOOKS

Dr. LICKLEY, in *The Nervous System*,[7] has brought his small book thoroughly up to date, although it remains much the same size. To anyone accustomed to the wealth of detail and excellent diagrams of Tilney and Riley's big book on the nervous system it comes as a welcome relief to find a British book which, while very much smaller, can still provide us with the same quality of diagram. For students of psychology it is probably quite large enough, but for students of neurology and of psychological medicine it is too condensed. The chapter dealing with the chief fibre systems of the cerebro-spinal axis is very well done indeed. The diagrams showing the crossing of the systems, and the schemes provided with these diagrams, are alike excellent.

The *Transactions of the Medico-Legal Society*[8] for the session 1929–30 consists of seven papers, the first of which is Lord Riddell's presidential address on ancient laws and modern women. Most of the papers provoked lively and informative discussion. Mr. Llewellyn-Jones surveyed the work of the League of Nations in the international control of dangerous drugs, and Dr. Lionel Weatherly gave some reminiscences from fifty years' experience as a medical witness. Papers were also read by Lieut.-Colonel Henry Smith, Dr. A. Knyvett Gordon, Dr. C. Ainsworth Mitchell, and by Professor John Haldane, who discussed carbon monoxide poisoning, with special reference to its medico-legal aspects. The volume is illustrated by a photograph of the president's badge, which represents Truth being drawn out of the Well of Life by Law and Medicine, combining in the cause of Justice.

The series of six lectures on *The Difficult Child*,[9] which was delivered under the auspices of the Jewish Health Organization of Great Britain, at Toynbee Hall, London, in May and June, 1930, has now been reprinted as a pamphlet, which will be of value to those who are interested in the medical, psychological, and sociological aspects of the problem of maladjusted children.

The appearance of the eighth edition of *The Mothercraft Manual*,[10] by Miss MABEL LIDDIARD, the matron of the Mothercraft Training Society, within eight years of the first publication of the work, is sufficient evidence of the well-merited success of this little book, which is an outline of the principles of Sir Truby King, the founder of the society.

Since the appearance of the original monograph upon *The Anopheline Larvae of India, Ceylon, and Malaya* in 1927, many new species and varieties of anopheline mosquitos have been recorded, and further knowledge has necessitated some emendations in description and classification. The present pamphlet, entitled *The Anopheline Larvae of the Countries from India and the Orient to the Antipodes*,[11] by Professor C. STRICKLAND and Dr. K. L. CHOWDHURY, forms a supplement to the previous work embracing these additions and corrections, and at the same time covers a wider geographical area, to include the Far East and the Antipodes.

In the collection of small, paper-backed "Introductions to Medicine," edited by Sézary and published by Masson, the volume on the pathology of the liver and pancreas[12] has been written by the sure hand of MARCEL BRULÉ. These small volumes are interesting, and have the great merit of being written by recognized authorities on the subjects. They certainly give a far better account than is obtained, for instance, in a chapter of one of the large textbooks of medicine so commonly read by medical students in this country. Brulé covers his subject fully in about 140 short pages, easily read and clearly divided into brief sections and paragraphs. The wording is clear-cut and dogmatic, as is necessary for the introductory function for which the series is meant; but these small, cheap, and easily kept up-to-date volumes are really useful to medical students.

SOVIET MEDICINE AND HYGIENE

Impressions of Medical Tourists in Russia

A meeting under the auspices of the Society for Cultural Relations between the Peoples of the British Common wealth and the Union of Socialist Soviet Republics took place at the London School of Tropical Medicine and Hygiene on November 23rd, when three members of the party of thirty doctors and scientists who recently visited the hospitals and medical institutions of Soviet Russia gave an account of their experiences. The chair was taken by Sir SQUIRE SPRIGGE, Editor of the *Lancet*.

Dr CLIFFORD ELLINGWORTH, medical superintendent of Queen Mary's Hospital, Sidcup, said that he quickly found on entering Russia that it was of no use trying to understand medical conditions in that country to-day without having regard to the conditions under the Tsarist regime. It would be unfair to judge present standards in Russia by those obtaining in England. Compared with English conditions the state of affairs in Russia was not wonderful, but when the dreadful conditions of the past were remembered, the mighty effort which had been made by the Russian people to set their house in order was wonderful indeed. In the past there was no central public health organization; there were odd hospitals run by charity in the larger cities, to which the people dreaded to go on account of the appalling death rate of 27 per cent., and the priests kept the people very much in ignorance of health as well as of other matters. Nowadays the people were learning physiology, hygiene, and the care of their bodies, things entirely new to the peasant class of Russia. A tremendous revolution had been effected by Dr. Semashko, the people's commissariat of public health in Moscow, who worked out a great scheme for the treatment of abortion. During the revolution it was decided that abortion was no longer illegal with the result that quacks immediately sprang up everywhere and the death rate due to improper abortions became very high. The Government thereupon decided to set up a number of abortion clinics. The procedure was for a woman, whether married or single, who found herself pregnant, to go to a local doctor, with whom was a committee of two representatives of the workers, to whom she put her case under the two headings of medical and social or economic. The doctor, if satisfied, gave her a certificate to attend the abortion clinic. The first day there was spent in rest and education. The woman was shown exactly what was proposed to be done to her. Some wax models, in life size, of a sagittal section through the female pelvis were exhibited, and the operation which was to be performed was explained. She was then shown various contraceptive methods, and a very explicit talk was given to her about their use; there was no mock-modesty whatever. A notice over the door stated: "You are welcome this time, but you are not expected to come again." The operation was performed next day, taking about three minutes, without an anæsthetic. As many as 70,000 official abortions took place in Moscow last year without one death; there were also 60,000 births. Another interesting point in the Soviet regime was the rescue of prostitutes, which was now a State procedure. Homes were established to which the women, most of whom were suffering from venereal disease, were received, medical attendance was given, and they were taught a trade. As a result of this movement the maximum number of prostitutes on the streets of Moscow was stated now to be 400, instead of 2,000, as it was two or three years ago. One of the most interesting features of medical life in Russia was the attitude of doctors towards the new system. Some time ago a medical workers' trade union was formed, which included orderlies, porters, ward maids and so forth. The doctors at first did not want to come in, but it was finally agreed that the doctors should join the union, but should be allowed to have a doctors union within the larger organization. In consequence the doctors now got "A" class food tickets, and were described as "worker intelligentsia." So long as they had refused to come in they were called "bourgeoisie," and only got "C" class food tickets, which meant that they did not have enough to eat. Until 1918 there was no such thing in Russia as State health insurance. That had now come into being and a committee was formed to grant allowances to people during protracted illness, which was thought better than continuing a salary because it led to encourage malingering. Of the applicants for sickness benefit in Moscow 50 per cent. were found to be suffering from tuberculosis. Magnificent night sanatoriums, of 45 to 50 beds, attached to blocks of flats and hospitals had been established, in which people threatened with tuberculosis, and living at home under unhygienic conditions, could spend their nights. The patient, after his day's work, was shown into a clean room with a window open, he would not close; he had a hot meal, listened to a lecture on personal hygiene or perhaps was entertained by music or the cinematograph and next morning had a hot breakfast before he went to his work. He might continue at the sanatorium for two or three months without ceasing to be a wage earner. The speaker had been struck with the slovenly condition of the beds in Russian hospitals, but it was not the Russian custom to make the bed every day, so that made it in hospital. There one had to qualify things very much, and not to be too intolerant in one's outlook. The dirty condition of the beds in Russian hospitals was one of the greatest obstacles which the new regime had to overcome. Lenin once said, 'A dirty peasant threatens to conquer Socialism,' and it did. The health department had included alcohol among the scourges to be fought, ranking it with syphilis and tuberculosis. During the last year or so 60,000 illicit stills had been seized. The speaker praised highly the organization of 'prophylactoriums,' as they were called. In one of these places as many as 2,000 out patients were treated daily by appointment, without waiting. Provision was made against any possibility of the out patient attending different hospitals in turn; the district nurse accompanied him to the department heard the instructions given and was able to see that the instructions were carried out when the patient got home. He thought that much was to be learned in this country from the conditions of out-patient work in Russia.

Dr HILDA STOESSIGER said that there were many things which could be criticized in the Russian system, including the lack of free choice of doctor inherent in any public scheme of medicine, but it was evident that Russia had gained a great deal from State control. Medical research was being encouraged. Most specialists appeared to devote a definite period each day to it, usually the afternoon, while the morning was spent in seeing the patients. Every part of Moscow was divided into small districts, each with its doctor and nurse or social worker, and these districts were linked up into larger ones, provided with prophylactoriums. One serious difficulty was that since the revolution Russia had been cut off from centres of medical thought. At most of the hospitals the doctors realized their isolation. A few foreign journals were seen, but not enough for detailed research in any particular subject. Here and there the party saw a survival of antiquated theories and methods of treatment such as the administration of electric shocks for curing hysterical attacks and habit spasms, and rather fantastic ideas for the cure of arthritis. But she was amazed at the amount of modern apparatus in use much of it made in Russia and the rest bought in Germany or Austria. At the Metchnikoff Hospital deep x ray apparatus of the latest pattern had been installed and 400 mg. of radium was in use; but in that hospital all the cases of cancer appeared to be in the advanced stage and one felt that the surgeon did not very often get a chance of doing a really radical operation on an early case. There were said to be about 40,000 doctors in the U.S.S.R. for a population of 160,000,000. The large hospitals in Leningrad and Moscow appeared to be staffed as adequately as our own and many medical men were working in laboratories so that it must be conjectured

that in rural districts there was great scarcity. Of the new medical students 40 per cent. were peasants from the collective farms. There was a shortage of drugs. Quinine was extremely scarce, and was reserved for the malarial districts of the Volga and South Russia. The Government was itself preparing gland extracts, serums, and salvarsan and bismuth preparations. The importation of vaccines was now prohibited. One of the party fell ill at Tiflis, and although he was attended by three Russian and three German doctors the very greatest difficulty was experienced in finding a chemist who could dispense the prescriptions.

Dr. EDWARD MAPOTHER, medical superintendent, Maudsley Hospital, gave some account of the arrangements in Russia for the prevention and treatment of mental disorder. He saw very little in his own line in Russia, and that little did not impress him at all. He heard a good deal more, but did not find all of it convincing. But it was only fair to say that if one took at face value all that one was told about the present aims of Russian psychiatry, it sufficed to explain in great measure the absence of anything in the way of special structure to show the visitor. The programme, which was one of considerable interest, was propounded to him by Professor Rossenstein, director of the Moscow Institute of Nerve Prophylaxis, who was largely responsible for it. It represented a sort of selective synthesis of arrangements in other countries. There were two main schools of Russian psychiatry. The Leningrad school, which for a long time was led by Bechterev, had always been mainly interested in the theoretical aspect. Its aim was towards the identification, as far as possible, of psychiatry with organic neurology. Recently it had been dominated by the influence of the work on conditioned reflexes and their inhibition, carried out by Pavlov and his school. This influence had gone so far as to lead to the proposed abandonment of psychology and the psychological approach in psychiatry, and the replacement of this by a science termed reflexology, which aspired to account for human behaviour without reference to consciousness. The other school, that of Moscow, in which formerly the outstanding figure was Korsakov, claimed to have been always more interested in the practical than in the speculative side of psychiatry. Its tendency was towards maintenance of very close contact with general medicine and other branches of State medicine, and through its influence it had come about that the existence of at least a psychiatric out-patient clinic was almost universal at Russian general hospitals. There was no doubt of the growing influence of psychiatry in Russian life. The whole movement was towards a reduction of the importance ascribed to heredity and towards regarding mental disorder, of whatever kind or degree, as representing rather an interaction between the individual and his environment. In psychiatric practice the tendency was towards what was termed "psycho-hygiene"—that is, the maintenance of psychiatric supervision even over persons reputed healthy, such as factory workers and students. Child psychiatry was handled apart from adults, and all school children and young people employed in industry were under the supervision of a central psychiatric organization, and were subjected by it to annual examination. Nervous and "difficult" children were dealt with by child guidance clinics. Psychiatry played an important part in the administration of the law, the psychiatrist acting at the police courts and also at the adjoining dispensary. With regard to the provision of institutional treatment for mental disorder, arrangements in Russia were grossly defective. Out patient clinics were excellent supplements to residential institutions, but they were not substitutes. At Leningrad he visited the Belinski Hospital, reputed to correspond to the psychiatric clinics of other countries. In structure, decoration, and comfort generally it was deplorable. It was true that a spirit of keenness and good scientific work might exist under such conditions, but from the standpoint of the patients there was little to be said for it. In Russia, with a population of 160,000,000, there were only 40,000 mental hospital beds; in other words, the ratio of beds to the population was about one-twelfth of that which existed in England. He thought it might be taken that there was no corresponding difference in the incidence of insanity. The annual admissions in Russia numbered 58,000. The shortage of beds was met by various devices whereby the insane were returned to live in the community, some to special hostels, some boarding out with sane people, others sent back to their families. For a certain number of cases such a system had merits, but he thought there was little doubt that it was being carried to excess in Russia.

NATIONAL BIRTH CONTROL ASSOCIATION

ADDRESS BY PROFESSOR LASKI

The first annual meeting of the National Birth Control Association was held at Caxton Hall on November 23rd, when Professor H. J. LASKI gave an address. The chair was taken by the president, Sir THOMAS HORDER, Bt., M.D., who, in introducing the lecturer, commented on the affiliation of the association with the Birth Control Investigation Committee, and said that indiscriminate childbearing, while it might be a disease of the human body, was certainly a disease of the body politic.

Professor LASKI inquired into the place of this movement for birth control in the kind of democratic society to which its members belonged, and recalled that the movement in England had begun as a protest against the privileges that belonged to the rich in an aristocratic society. The association ought humbly to remember, he said, the debt it owed to pioneers who had set an example of insight, courage, and determination. To the lecturer birth control seemed essentially part of the general process of civilization. It was inevitable at some period in evolution that intellect should replace blind impulse in the control of sexual relations. It was impossible to limit the range of anything so explosive as knowledge. Society of to-day could allow birth control to percolate to the working classes by accident, but such a course would do illimitable and profound harm. On the other hand, it could extend that knowledge as part of a deliberate effort to plan civilization, as part of the birthright of every civilized man and woman. The control of the problems of population would place in the hands of society a weapon of as great significance as that conferred by the discovery of fire.

THE CASE AGAINST BIRTH CONTROL

The first objection raised by opponents was the religious objection. Professor Laski denied that a society which had become by the nature of its being a secular society, independent of any form of religious organization, could allow the theses of any particular religion to determine the life of the State. He characterized the religious objection as the attempt of a minority to dictate to the majority. The advocates of birth control did not ask that they should be allowed to affect the individual life or practice of any member of a religious body, and equally in return they asked that the religious bodies should refrain from seeking to determine the conduct of the State. The second argument was political: that birth control would challenge the power of the country and, indeed, of Western civilization; that to avert perils to culture, notably from the East, Western civilization must multiply—as it had been put—like the sands of the seashore. In reply to that he declared that, given the weapons now at the disposal of the forces of conflict, those who thought in concepts of power were inviting the perpetuation of a philosophy which would make the whole of civilization a legend. It was essential to think in terms of the end that civilization was seeking. Moreover, civilization depended not on the quantity of the mob, but on the quality of the brains at its disposal. The third argument against birth control was that it endangered the basis of morality. Speaking as a historian, he resented the ignorance of those who argued thus. Morality was no unchanging concept. It had not been the same in Athens as in the present century; it was not the same in Russia to-day as in the United States to-day. He urged his audience to emulate

the British Empire, which could emphasize the unlimited character of its faith in monogamy in Great Britain, and at the same time in the remoter confines of its dominion could proclaim that it would stand by the right of alien faiths to practise polygamy, without a blush upon its noble features. As the environment changed, concepts changed to suit the environment, and the notion that one could arrest social evolution at a moment suitable to one's self was futile. Nothing was more dangerous than to make one's private principles the measure of public conduct.

PRINCIPLES JUSTIFYING BIRTH CONTROL

The mere conflict of private wits would never produce a well ordered commonwealth, and to leave relationships between men and women and their community to blind impulse must mean pain for the individual and disaster for the commonwealth. Birth control was a process of emancipation, particularly for women, but also for children and for men. Professor Laski urged the difference between the average working girl at 19 or 20, and the same woman at 25 or 26, after a few years' experience of her obligations as a married woman. She was an unpaid domestic servant with a right to sit in the best room in the evening, if there was a best room, when the day's work was done, if it ever was done. To give such a woman conscious control of parenthood was one of the most considerable pieces of liberation that had ever come to the human race; it would make her for the first time in history a person able to think—a service of the first order to the quality of national life. If the child of the next generation was to be educated, it was essential to set it free from the situation it occupied in the overcrowded or parentally negligent home. Half his problems as a teacher were the problems of the parent of explaining that the basis of a university was not to train students for anything—particularly for earning anything—but to assist them in the process of learning what thought was. The problem was still more serious in secondary education, and much more so in primary education. Only by arresting the torrent of children in overcrowded homes could education march to the end that education had to serve. It was the business of educationists to persuade men and women into the habit of intelligent doubt. The tragedy of this civilization for men was that they were thought of so predominantly as wage earners. Material value had become the measure of what was meant by manhood. Too many leaders were occupied by the search for economic or political power and did not know that progress in the realm of power rested on a basis of knowledge of civilization and not on the power to dominate in the terms of a narrow conception. In the positive sense, Professor Laski doubted whether anyone had the wisdom or insight to know what type it was eugenically desirable to breed. He sometimes believed it possible that the failure of the academic classes to perpetuate in adequate numbers was going to be one of the sources of refreshment of the national quality in years to come. In the negative sense, however, he could only regard it as a policy of sober sanity to prevent the multiplication of imbeciles, haemophiliacs, and deaf-mutes.

THE OBLIGATIONS OF SOCIETY

The first duty of society, he said, was to make possible medical research in birth control, a function which ought to be assisted just as much as research into cancer or tuberculosis. Secondly, it was the business of the State to make available a full supply of cheap birth control clinics all over the country, above all as an essential and integral part of the normal service of maternity and child welfare. It would be fatal to regard birth control as something unrelated to the general process of safeguarding the quality of the wives, mothers, and children helped at infant welfare centres. Thirdly, it was the business of society to ensure that a proper knowledge of the latest developments in birth control was part of the curriculum of the medical student. Every curriculum was overcrowded, but the doctor here had an obligation of so supreme a character that he was denying the whole basis of his profession if he had not this knowledge. It was futile to think that this movement could possibly be prevented from moving relentlessly to its conclusion, or to deny to men and women knowledge that they had come to realize was essential to the assertion of their personality. The relation of the birth control movement to the philosophy of freedom, and the relation of the philosophy of freedom to the preservation of individuality, made birth control one of the two or three things that were essential to freedom. The road was still long and full of difficulty, but the very complexity of the adventure gave it its character of nobility.

SIR THOMAS HOPDER pointed out that before anything could be done to modify the medical curriculum, it was necessary to convince society, first that it had a disease, and secondly, that it wanted to be cured. He himself viewed indiscriminate child bearing as a disease, and was therefore very anxious that instruction in birth control should be included in the medical curriculum as soon as possible. It was the duty of the medical profession to devise, improve, and teach the remedy; it was for such as Professor Laski to show the extent of the disease and what would happen if it could not be cured or to a large extent palliated.

IMPERIAL CANCER RESEARCH FUND

ANNUAL REPORT

The twenty-ninth annual report of the Imperial Cancer Research Fund was published last week. After mentioning certain changes on the staff and committees it refers briefly to some of the work accomplished during 1930–31. A course of lectures on cytology was delivered by Dr. Ludford at University College, and four advanced lectures were given by the Director, Dr J. A. Murray, and Dr W. Cramer. For one month of the year the laboratories secured the services of Professor Robert Chambers of New York, who will be recalled as a pioneer worker on micro-dissection and micro-injection. A full explanation of the technique of his methods was thus available to members of the scientific staff. Eight papers were published from the laboratories during 1930–31, while the considerable interchange of tumour material with research centres in this country and on the Continent affords evidence of the close contact maintained with other workers on cancer. Scientific details are embodied in the report of the director, which concludes with the following remarks:

"This discussion, taken in its entirety, leads to the conclusion that we are not yet in possession of such knowledge of the properties of the cancer cells as would indicate clearly the direction in which a rational specific therapy of cancer should proceed. It is perhaps not too much to hope that these observations may help the lay and general medical public to appreciate the conservative and cautious attitude which those engaged in cancer research preserve towards the recurring extravagant announcements of new methods of treatment for cancer. In particular we should recommend that the layman should finally discard his attitude towards this medical and biological problem as a gamble, where success is equally likely to fall to the ignorant as to the instructed. This betrays a profoundly mistaken view of the nature of the cancer problem. Thirty years of cancer research have revealed that this problem possesses a complexity which was quite unexpected. The knowledge which has thus been gained justifies the hope that perhaps progress in the direction of an efficient cancer prophylaxis is possible. An advance along such lines is, however, not dramatic or sensational. But whatever the future of the cancer problem will be, it is certain that it will not yield to the sound of a trumpet."

GENERAL COMMITTEE MEETING

At a meeting of the General Committee held on November 25th, with the PRESIDENT the Duke of Bedford in the chair, Sir HUMPHRY PAGESTON, chairman of the

Executive Committee, moved the adoption of the twenty-ninth annual report of the Fund. He first drew attention to the preparation of the tenth Scientific Report, which would deal mainly with the work in progress during the last two years and more, on the mode of action of radium on malignant growths, principally in small laboratory animals. The Executive Committee had been kept informed from time to time of the progress of these investigations, and felt sure that their publication, in detail, in one volume would be a useful contribution to the knowledge of this difficult subject. Passing to a summary of Dr. Murray's report for the year, Sir Humphry Rolleston said:

"The remainder of the Director's report falls into two parts, in the first of which attention is drawn to Dr. Cramer's papers on susceptibility to cancer as applied to the important subject of the incidence of cancer of the stomach in this and several European countries. Although the total incidence of cancer in males is approximately the same in these different communities, only 25 per cent. of male deaths in England and Wales are due to cancer of the stomach, whereas the proportion in the European countries from which accurate statistics are available is as high as 50 per cent. or more. This discrepancy is accentuated when the incidence in different social classes in the same country is compared. In England and Wales, as Dr. Stevenson showed, cancer of the stomach and upper alimentary tract is more common in lower social classes, the incidence of the lower alimentary tract being the same for all classes. In Bavaria, with double the frequency of gastric cancer in the whole male population as compared with England and Wales, the proportion in the working classes is from 60 to 70 per cent. of total cancer deaths. From the analogy which these facts of the incidence of occupational present to the conclusion is drawn that the important factors cancer, the conclusion is drawn that the important factors in producing this remarkable result are external, bound up with the habits of the social levels involved, and avoidable. As these vagaries in organ incidence of cancer do not produce corresponding fluctuations in the total incidence of the disease in the populations under review, the plus for one organ is reflected in a minus for the others. Thus, according to the statistics, cancer of the tongue is nine times more frequent in England than in Bavaria. It is as if the majority of cancer deaths fell on a susceptible fraction of the population (roughly 10 per cent.), the members of which respond relatively easily, by manifesting cancerous growths, to forms of chronic irritation to which the whole population is exposed to much the same extent. Susceptible individuals, fortunate enough to escape the full brunt of these irritations, may escape, and, conversely, excessive irritation may lead to cancer development in a small proportion of individuals constitutionally unsusceptible. The second part of the report deals with the results of Dr. Ludford's investigations into the action of dyestuffs and metallic colloids on cancer. In the twenty-seventh annual report reference was made to the difference between normal connective-tissue cells and the corresponding malignant cells (sarcomata) towards the colloidal dyestuff trypan blue, in that the sarcoma cells remained uncoloured under conditions in which the normal cells were deeply stained. The cellular mechanism involved in this reaction, known as vital staining, was investigated, and evidence has been obtained that the difference noted between normal and malignant cells is not due to failure of the dyes to reach the cancer cells, but to special characteristics, apparently peculiar to cancer cells, which are still the subject of investigation. The possibility that dyestuffs, metallic colloids, and other chemotherapeutic agents may influence the growth of cancer indirectly through an action on the organism of the host, has led Dr. Ludford to investigate the action of these substances on the resistance to transplantable tumours. In effect, it has been found that one of the carcinoma strains, which in untreated animals grows only temporarily and then regresses, can be made to grow progressively by treating the mice bearing it with trypan blue or metallic colloid. The immunity to transplantable growths, which can be induced by preparatory injection of emulsions of embryonic tissues, can be broken down by similar injections of dyestuffs or colloidal metals. The doses necessary to produce this result must be large—approximately the limits tolerated by the animals. These results emphasize the dangers of over-dosage in the treatment of cancer with toxic colloids in that the natural reactions of the body may be so modified as to accelerate the progress of the disease. The converse process of raising instead of lowering the natural resistance to such an extent as to retard or arrest the growth of cancer has so far not been attained in these experiments. It remains a fascinating aspiration. The report concludes with a summary of the evidence, from these and other investigations, of the enhanced defensive mechanisms of the cancer cells. Their relative independence of oxygen supply and indifference to concentrations of poisonous substances, such as carbon dioxide, which are lethal to normal cells, are paralleled by their resistance to such physical agencies as heat and cold. The action of radium probably does not provide an exception, as there are many well-authenticated instances of progressive growth or recurrence of cancer after intense radiation. In fact, though there are many examples of the greater viability of cancer cells as compared with the normal, there is no evidence as yet available of a single property in which they are more vulnerable. This may sound pessimistic, but if it is true there should be no need to insist on the dangers of underestimating the enemy. The knowledge attained during the past thirty years is already indicating the broad lines along which prevention of cancer must proceed. The immediate problem of a rational treatment remains."

In a speech moving a vote of thanks to the chairman and members of the Executive Committee and others who had assisted in carrying on the work of the Fund during the past three years, the PRESIDENT (the Duke of Bedford) referred to the loss of Lord Balfour, who had been a vice-president of the Fund since its inception in 1902. Another loss was that of Sir Anthony Bowlby, formerly President of the Royal College of Surgeons, and up to his death a valued member of the Executive Committee. The financial position was as satisfactory as could be expected under present-day conditions. The president referred to the generosity of Lord Atholstan's grant of £2,000 a year for ten years, which, although it had now come to an end, had made possible the establishment of a second laboratory outside London. Thanks were also due to the executors of Sir Otto Beit for a legacy of £8,000. Though the Fund was still dependent on legacies, donations, and subscriptions, he trusted they might be able to carry on without lessening their work and activities. In conclusion, the President conveyed the best thanks of the Fund to Dr. Murray and his staff for their excellent work. Dr. Murray had a most extensive knowledge of his subject. He was always willing to place his experience and material at the disposal of investigators at home and abroad, and to lend a helping hand to younger men in research work. He was always ready to welcome and explain to visitors from all parts of the world—Europe, America, and the Far East—the work carried on in the laboratories, and in this he was greatly helped by his linguistic attainments. He had an able assistant in Dr. Cramer, and the members of the scientific staff, who were working keenly with the determination that although the quest was long, they would know no end but success.

Sir Alfred Lane Beit was then elected a vice-president of the Fund. Professors A. E. Boycott and W. Bulloch were re-elected members of the Executive Committee, Sir John Rose Bradford being made an additional member. Sir Percy Sargent was appointed joint treasurer of the Fund with Sir George Makins. Lord Dawson of Penn moved a cordial vote of thanks to the Duke of Bedford for presiding at the meeting, and this, seconded by Sir BASIL MAYHEW, was carried with acclamation.

L. N. PYRAH & P. R. ALLISON: SOME SIALOGRAMS

FIG. 1.—Sialogram of normal parotid gland.

FIG. 2.—Sialogram of normal submaxillary gland.

FIG. 3.—Case I. Chronic parotitis. Bronchiectatic like dilatation of terminal ducts and alveoli.

FIG. 4.—Case II. Showing saccular dilatation of the intraglandular part of Wharton's duct with deficient filling of finer ducts.

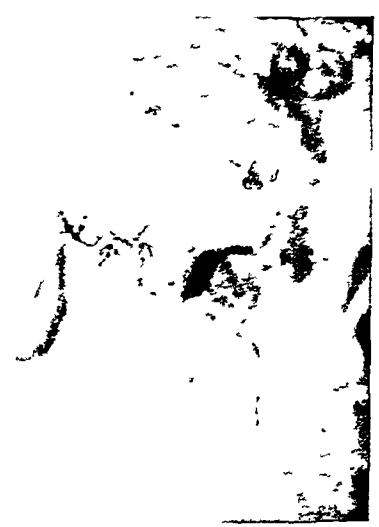

FIG. 5.—Case III. Normal sialogram of right submaxillary gland immediately anterior to which is a faint shadow of a mass of tuberculous lymph glands.

FIG. 6.—Case IV. Parotid abscess with destruction of the gland. Showing obliteration of all but the main parotid duct.

FIGS. 1 AND 2.—Two films of the barium enema examination of December 30, 1930. The loop of the sigmoid colon is shown drawn over to the right iliac fossa. In Fig. 2, the loop is seen in close proximity to coils of the ileum. Two long diverticula are seen attached to the loop on the right side, and numerous diverticula on the left. There is a "defect" shown in the loop on the right. This part of the bowel was very much thickened at operation and the perforation occurred from the diverticulum at that site.

FIG. 3.—Twenty-four hours' barium meal. The outline of the sigmoid can be made out; it is drawn to the right. Numerous diverticula are shown.

FIG. 4.—Barium enema of February 13, 1931. The sigmoid loop is now shown well over to the left. Several long diverticula can easily be seen.

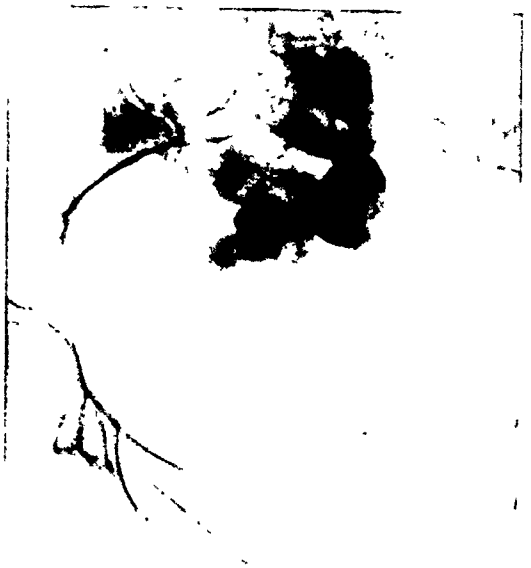

FIG. 1.—Radiogram of the pelvis of a woman aged 34, who suffered from pain in the lumbar region and left iliac fossa, associated with increased frequency of micturition, pyuria, and occasionally haematuria. There is a dense shadow of an object lying in front of the sacrum.

FIG. 2.—A cystogram. The bladder has been filled with a 7 per cent. solution of sodium iodide and the exposure made. The bladder is clearly outlined and is seen to be distinct from the other shadow.

FIG. 3.—Ureteric catheters have been passed and 12·5 per cent. solution of sodium iodide injected up them. The pyelogram of a normal left kidney is seen. On the right side the catheter has passed inwards over the shadow, and a little of the sodium iodide has passed on from the catheter to the object.

FIG. 4.—The ectopic kidney split open and mounted after its removal from in front of the sacrum.

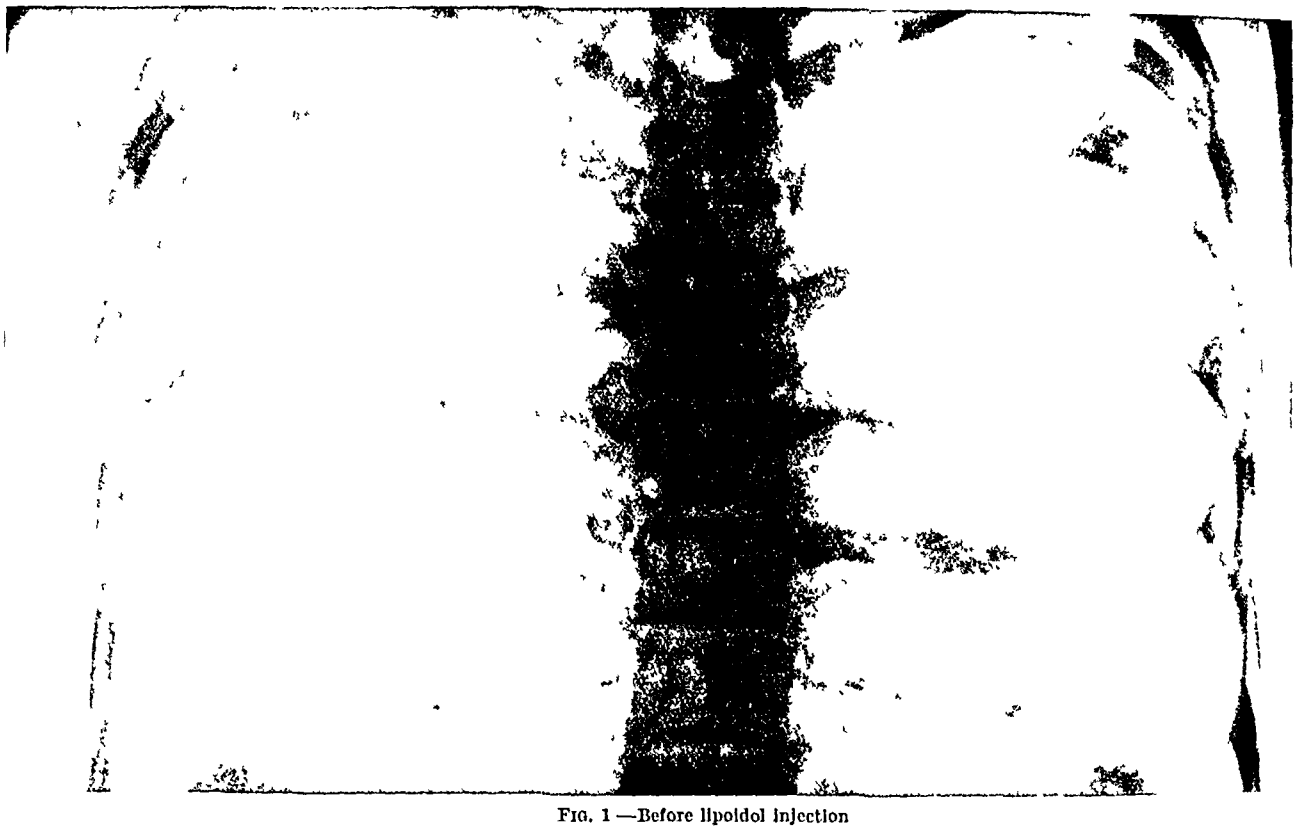

FIG. 1.—Before lipoidol injection

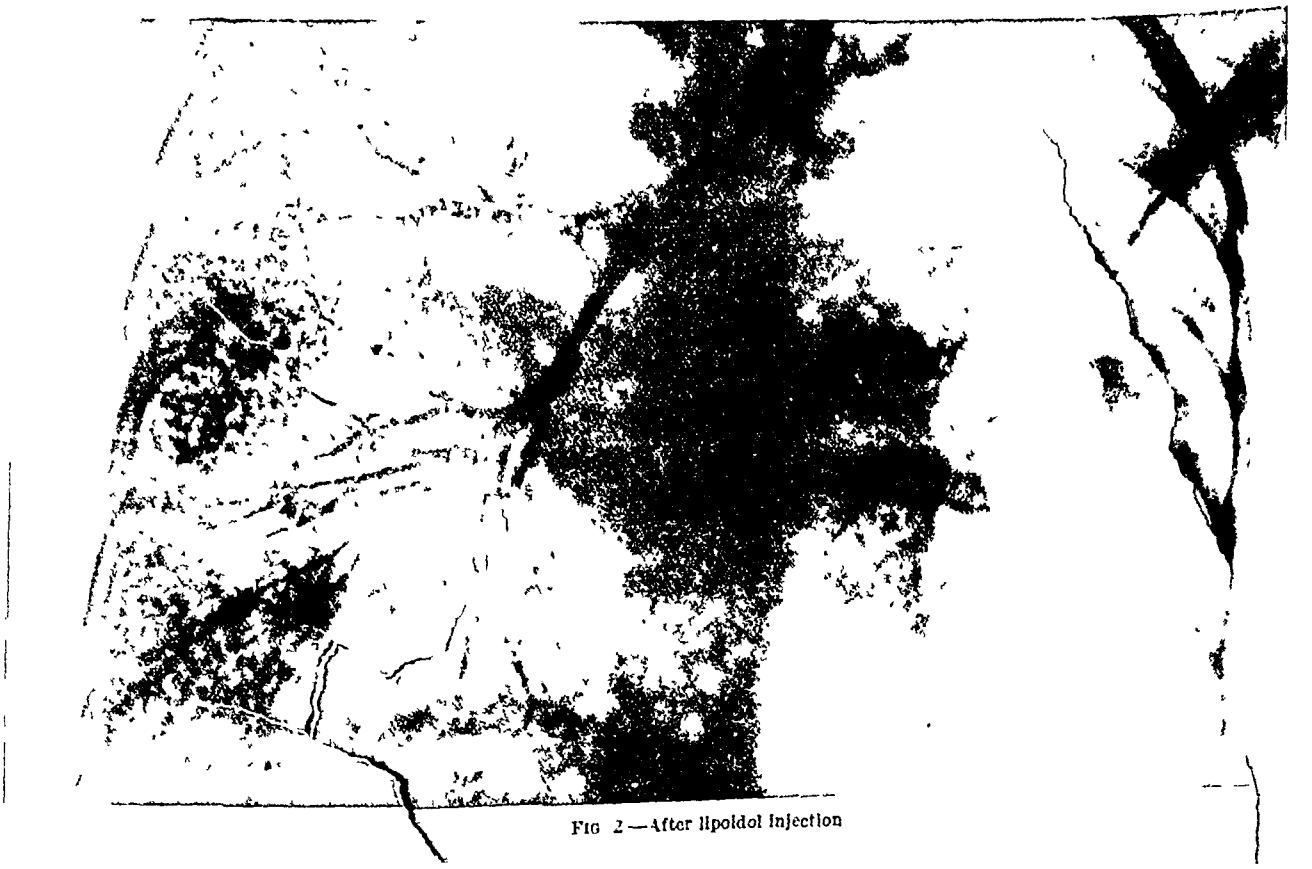

FIG. 2.—After lipoidol injection

British Medical Journal

SATURDAY, DECEMBER 5th, 1931

THE ASSOCIATION'S CENTENARY

The British Medical Association was founded by Sir Charles Hastings at Worcester in the year 1832. The only qualification which this statement requires is that the Association at first existed under another name (the Provincial Medical and Surgical Association), and that at the date in question Charles Hastings had not yet received his knighthood. The centenary of the Association falls due, therefore, next year, and its celebration in July will rank as of great importance both in the history of medicine and among the public events of 1932. To the members of our calling it will commemorate the first practical step taken towards professional unity and towards that formal unification of the profession which was not, in fact, accomplished until the passing, twenty-six years later, of the Medical Act of 1858. From a wider standpoint it will remind professional men and women generally, and other members of the public, that the British Medical Association was a pioneer in that movement towards forming vocational organizations which manifested itself during the middle half of the nineteenth century, and had such a powerful effect, not only upon the evolution of the professions themselves, but upon the development and well-being of our whole social structure. The former aspect may be exemplified by quoting the main object for which the Association was originally formed—namely, "the maintenance of the honour and respectability of the profession generally by promoting friendly intercourse and free communication of its members, and by establishing among them the harmony and good feeling which ought ever to characterize a liberal profession." The second aspect is best illustrated by a reference to the valuable Herbert Spencer Lecture delivered at Oxford in 1928 by Professor Carr-Saunders, and published at the Clarendon Press under the title, "Professions: their organization and place in society." Study of his interesting pamphlet will elucidate and emphasize the importance of the centenary in this respect.

In yet another of its aspects the centenary celebrations will form a noteworthy national and imperial event. The membership of the Association, while large absolutely (some 36,000), includes a very considerable proportion of the medical practitioners in all branches of the profession in Great Britain, Ireland, the Isle of Man, the Channel Islands, and, with the affiliated Canadian Medical Association, an even bigger proportion of those practising in the Dominions, India, the Colonies, Dependencies, and Mandated Territories. There is no doubt that, in spite of adverse economic conditions, a large number of members from over-seas will be present to take an active part in the proceedings in London next July. Moreover, it is confidently expected that foreign medical societies, colleges, and universities will send delegates with greetings to their British colleagues. The ceremonies will thus afford no mean demonstration both of the common interests and feelings of all parts of the British Empire, and of the fact that the fraternity of medicine and the allied sciences contributes much to international understanding and good will.

Active preparations for the meeting on its social, medico-political, and scientific sides are now in progress. The actual hosts on this occasion are the members of the Metropolitan Counties Branch (that is, those members living within the area of the County of London, the county of Middlesex, the county boroughs of West and East Ham, and the adjacent portions of South-West Essex), though the central officers of the Association will participate in larger measure than is usual at an ordinary annual meeting. Members of the Worcester Division are also directly concerned in one part of the programme. The Representative Body of the Association will meet at the headquarters in London on Thursday, July 21st, and its deliberations will probably continue until Monday, July 25th. It is likely that several of the subjects under consideration will be of exceptional interest. The Centenary Meeting proper will begin on Sunday, July 24th, with a pilgrimage to the city of Worcester. By invitation of the dean the official religious service will be held in the cathedral, where, during the few hours to be spent in the city, a stained-glass window to the memory of Charles Hastings will be unveiled. A commemorative plaque on the house where he lived and practised will also be unveiled, and a visit may be paid to his grave. It is perhaps not out of place to remind members and friends of the Association that contributions, of a guinea or less, will be welcomed to the relatively small Sir Charles Hastings Memorial Fund, which is required to provide both window and plaque, and to ensure permanent upkeep of the grave.

Lord Dawson of Penn is the President-Elect of the Association. He will be installed in office and will deliver his Presidential Address on Tuesday, July 26th. The scientific meetings, divided among twenty-four Sections, will begin on the following morning, some of the Sections meeting on one day only, some on two days, and some on three. For each scientific Section a distinguished president has been secured, who will be supported by two able secretaries, and by more than the usual number of eminent vice-presidents. These will be drawn in due proportion from London, from other parts of the British Isles, and from the Oversea Empire. It is anticipated that the scientific results of the work in the Sections will be of great value. The social features of an Annual Meeting—the annual dinner of the Association, Branch and other receptions—will be repeated on an ampler scale than is customary. A large and representative general committee, and a ladies' committee, are already getting to work so as to ensure

that every possible arrangement is made for offers of hospitality and for the reception, entertainment, and comfort of those who take part in this historic meeting. We can confidently ask for the interest and co-operation of all members in reinforcing the efforts of the Metropolitan Counties Branch and the Central Council to make the centenary week a conspicuous success.

TREATMENT OF STIFF JOINTS

In choosing this for the subject of the Mitchell Banks Memorial Lecture at Liverpool on November 19th, Sir Robert Jones was, as he told his audience, influenced not only by the words of Sir William Mitchell Banks, but by his own sense of the importance of the subject, and especially by that aspect of it which concerns unqualified practice. Sir Robert Jones takes a very serious view of the claims made by such practitioners and of the public's belief in their validity, based on cases of stiff joints resulting from a neglect by qualified practitioners of forcible manipulation and rupture of adhesions. He evidently holds that the public has some grounds for the distrust and even for the "open hostility" which he says it has displayed on occasions. We hope his modesty has led him to underestimate the effect of his own life-long teaching and of the spread of sound orthopaedic doctrine by his many disciples, who since the war have been scattered over the provinces engaged in the work of the cripples' hospital scheme, which owes so much to him. His lecture is the more welcome because, as he says, the ordinary surgical textbook deals with the problem of the stiff joint either not at all or at most indefinitely, and we would add that even in the textbooks on orthopaedic surgery it will be hard to find the equivalent of the knowledge and advice given in this address.

The crux of the problem will be found in the question of diagnosis, on which depends the decision whether to treat a stiff joint by rest or by movement. Broadly speaking, arthritis forbids movement, while adhesions require it. It is by studying Sir Robert Jones's lecture with care, and heeding his admonitions, that the reader will be enabled to decide, and, having made his decision, to leave few opportunities for the unqualified to triumph. We say advisedly "few opportunities" rather than none, for there will always be patients who neglect good advice when this is given by a medical man, but will accept it later when offered by an unqualified person. We must all, with Sir Robert Jones, recognize the therapeutic value to a neurotic patient of a positive assurance that the treatment will do good; but we do not think he means to imply that any medical man should say to his patient, "A vertebra is out, I will replace it," when an *x*-ray photograph shows no bony anomaly; although some readers might interpret Sir Robert's words as approving the *suggestio falsi* when he declares that, in the neuro-mimetic and the neurogenic, such a stimulus is an essential part of treatment. It is not so much in the joints of the limbs as in those of the spine, and especially the smaller joints, that even *x* rays may fail to elucidate the condition and leave the diagnosis obscure and the field open to the adventurous "hit or miss" manipulator, whether he be qualified or no. The example of a painful back, which the lecturer chose for the inculcation of sound principles of differential diagnosis, is a happy one, for it makes clear at once some of the essential symptoms of adhesions and arthritis. In rheumatoid arthritis and osteo-arthritis there are conditions in which certain movements are beneficial; but in adult stiff joints, caused by tuberculous infection, corrective movements are excluded, and the sooner an ankylosing operation on the ankle, knee, or hip can be performed the better, if amputation is to be avoided. The rooted objection of H. O. Thomas to the forcible correction of ankylosis had its origin in his experience of the disastrous results following the movement of tuberculous joints by bone-setters in his day. We are glad to learn that in the opinion of the lecturer such accidents, thanks largely to radiography, are now rare; but, in the absence of all statistics of the operations of unqualified persons, some doubt must remain on this point.

Sir Robert Jones has cast his net wide and included in this masterly summary all forms of stiff joint, acute as well as chronic. Perhaps those caused by rheumatic affections are the most disastrous in the disabilities and the sufferings they involve. If, unfortunately, it must at present be admitted that the causation of neither the hypertrophic nor the degenerative form is fully known, and that no method of preventive or curative treatment is generally successful, a good deal can be done to check the course of these diseases and to minimize their evil effects. On this head Sir Robert spoke decisively of the surgeon's duty to foresee that a joint is likely to become stiff, and to recommend measures that will ensure its fixation in the position in which the limb concerned will be most useful and least crippling to the patient. What these positions should be in the various joints he clearly indicates. This aspect of treatment of rheumatic joints has been much neglected, as a visit to any spa frequented by such patients will quickly show.

In the more severe cases of joint trouble, where there is obvious disorganization and loss of function, the bone-setter is generally wise enough to recognize his limitations and not to interfere. Such cases offer opportunities for operations which are planned to correct deformity, or to fix the joint and obviate painful movement, or on the other hand to restore movement by making a new joint in another place or by reconstructing a joint in its original site. Since the days of Gant, osteotomy of the femur has been widely practised with the purpose of correcting flexion and adduction deformity, and nullifying what is called "apparent shortening" of the limb. *Mutatis mutandis*, osteotomies are applicable to the other segments of the lower limb. Pseudarthrosis at or near the hip-joint may substitute a painless for a painful joint, even though the normal range of movement cannot be restored, and arthroplasty in suitable cases has enabled the surgeon

to go further in the same directions. For the latter operation at the elbow Sir Robert Jones claims that "we can almost promise a satisfactory result, good movement, and fair mobility"; but he prudently recognizes that in the case of the knee, arthroplasty is still in an experimental stage and only to be undertaken by the most expert surgeons on patients who are prepared to endure long and suffer greatly. If we have said little of stiff joints in the upper extremity and their treatment, it is not because we do not recognize their frequency and importance, but because we would refer our readers to the lecture itself.

BIOLOGY AND SOCIAL PROGRESS

Dr. H. H. Dale, in his Norman Lockyer Lecture, delivered before the British Science Guild, on "Biology and civilization,"[1] raises two questions of considerable interest at the present time—namely, whether the biological knowledge now available for the service of mankind receives the attention it deserves on the part of the community, and whether it is practically applied in a measure that might reasonably be expected. He thinks this is not so, and that the fact may have untoward consequences in the course of our progress in civilization. He gives illustrations of the evil results that are apt to follow changes in the physical conditions of human life and activity when they are made without thought of their biological implications. Our industrial system inflicted immeasurable misery in the shape of bad teeth and deformed limbs on several generations of those who served it, solely through an industrial development in advance of biological knowledge. In that instance, perhaps, the necessary knowledge was not available, but at the present day it is unnecessary to specify the innumerable directions in which acquired biological knowledge awaits application, or at least more effective application.

The application of the science lags behind general progress, and Dr. Dale indicates what he considers to be the cause of this. He believes that the influence of any movement in science on the general trend of our civilization is probably determined less by the reactions to it of professional men of science than by those of ordinary thinking men. He is of opinion that, in so far as general interest in science is concerned, it is at present unequally concentrated on the physical, to the comparative neglect of the biological aspect; and he regards this as a serious defect which is inevitably reflected in our educational and administrative systems. The inequality begins in our secondary schools; in these, although science is now recognized as a cultural factor, biology, if any provision is made for it at all, is hardly ever a part of the normal curriculum. Similarly with regard to the university career, a man may pass through his academic course to an honours degree in science, and so, perhaps, to a career in industrial research, with no opportunity whatever even for contact with biological ideas. "How," he asks, "shall the demand for biology be created to which education must in the end respond, while education continues to give us an administrative class with so little vision of the need for, and the central significance of, biological knowledge?" With ignorance and indifference on the part of our public men, the evil effects of progress conducted on non-biological lines will inevitably be repeated.

Dr. Dale concludes his lecture with a word of warning. If it is important that the findings of biological science should receive practical application, it is no less important to avoid their application while they are still in the experimental stage. "Nobody," he states, "can suggest that with our present knowledge we can predict even the initial stages of a strictly scientific application of genetic principles to the problem of improving the human species." Moreover, to advance such a suggestion, for example, as the intensive inbreeding of individuals showing favourable factors and the ruthless elimination of the rest—even if supported by complete scientific knowledge—would bring science into shattering conflict with our existing social order. Science has nothing to do with policy, and, moreover, its function is not to shatter, but to provide new and tested material for better building.

THE TRAFFIC IN NARCOTIC DRUGS

The report of the commission of inquiry into the control of opium smoking in the Far East, which was appointed by the Council of the League of Nations in March, 1929, provides valuable information, not only on the particular question contained in its reference, but also on the problem of opium and the traffic in dangerous drugs generally. It also serves to confirm the attitude which the *British Medical Journal* has consistently taken up during the last decade. The commission found that "the whole problem of poppy cultivation and its control enters very materially into the question of suppression of the opium-smoking habit"; that "as long as poppy cultivation is not under control there will always be illicit traffic in opium"; and that "the limitation and control of poppy cultivation will alone assure the total suppression of opium smoking." It will be remembered that the Hague Opium Convention of 1912 contemplated "the gradual and effective suppression" of opium smoking, and the prohibition of the traffic in prepared opium, either immediately or as soon as possible. The agreement arrived at in 1925 at Geneva pledged the Powers concerned, "on the grounds of humanity and for the purpose of promoting the social and moral welfare of their peoples, to take all possible steps for achieving the suppression of the use of opium for smoking with the least possible delay." Nevertheless, by protocol, the desired "suppression" was postponed to a period of not more than fifteen years from a date when a commission of the League of Nations should decide that the export of raw opium from poppy-growing countries would no longer constitute a serious obstacle to the reduction of consumption of prepared opium. The commission, while satisfied as to the evil effects—physical, mental, and moral—of opium smoking, could find no scientific evidence as to whether the smoking or the eating of opium is more

harmful to the individual addict. The danger of resort to other narcotic drugs, and the illicit traffic in them, came under consideration, and the fact that opium is a considerable source of Government revenue in Far Eastern territories was stressed by the commission. The broad generalization arrived at, as the result of the exhaustive inquiry, was that "the radical method of dealing with illicit traffic in opium is by controlling effectively the cultivation of the poppy, allowing only such quantities to be produced under international control as are required for the world's medical and scientific needs." Some idea of the extent of the subterranean trade in narcotic drugs has been conveyed to the public mind this week by reports of the sentences passed at Basel upon three traffickers in heroine.

DANISH ASTHMA STATISTICS

H. C. Gram has made a statistical study of 625 cases of asthma in a sickness insurance organization in Denmark.[1] The ratio of males to females was as 326 to 299, and a classification of the patients in 10-year groups showed that the disease began only in 78 in the first decade and only in 84 in the second. In the third decade there were 152, in the fourth 147, and in the fifth 105 patients whose symptoms of asthma first appeared at this age. In 515 cases information was obtained as to the hours when the attacks were most frequent; in 301 they occurred mostly at night, in 33 mostly by day, and in 181 as often by night as by day. Cutaneous tests with various extracts of foodstuffs, pollens, etc., were made in 188 cases. No reaction occurred in 97 of these, and a positive reaction was observed in the remaining 91. In 64 of the 91 reactors the reaction was positive to several substances; in the other 27 it was positive to only one substance. In 150 cases an attempt was made to correlate the results of the cutaneous tests with the patients' own experiences and beliefs as to the causes of their attacks, but in as many as 134 of these no positive correlation could be established. In 132 cases eosinophil leucocyte counts were made, and eosinophilia exceeding 4 per cent. was found in 59; in 15 cases it was 4 per cent., and in the remaining 58 it was less than 4 per cent. It would therefore seem that the diagnosis of asthma cannot be excluded because eosinophilia is absent, but when it is over 4 per cent., and when certain skin diseases and helminthiasis can be excluded, eosinophilia is confirmatory of a diagnosis of asthma. Diseases of the nose (polypi, rhinitis, etc.) were found in 45 cases. In none of the 25 cases in which polypi were removed was a permanent cure of the asthma effected. But the author considers operative intervention justifiable in such cases because nasal obstruction hampers the already embarrassed respiration and favours mouth-breathing, with its inhalation of dust into the lower respiratory passages. The degree to which the expectation of life may be reduced by asthma was calculated from the average duration of life, after the first onset of asthma, of 72 patients who had died. Up to the age of 50 the expectation of life was between 40 and 46 per cent. of the normal; after that age, when the patient's powers of compensation were comparatively small, the expectation of life was only between 22 and 29 per cent. of the normal. In 481 cases the occurrence of asthma in other members of the family was inquired into, with negative results in 211. In the remaining 270 cases (56 per cent.) with a family history of asthma there were 119 in which several relatives were asthmatics. The influence of heredity was demonstrated by a study of 71 patients in whose families more than one other case had occurred; in as many as 61 of these all the cases of asthma in the family were in one and the same branch of it. In a group of 504 cases information was sought as to factors which might have provoked the original attack, and in as many as 351 (69.6 per cent.), ailments such as influenza, pneumonia, severe colds, and bronchitis had preceded the first attack of asthma by a short interval.

HOUSING AND MALARIA

The importance of housing and its relationship to malaria has been recognized for many years since Manson's experiment in the Roman Campagna. The short critical summary entitled *Housing and Malaria*,[1] by Lieut.-Colonel Clayton Lane, which has been prepared for the Health Organization of the League of Nations, is of great interest and importance. After discussing the literature on this subject the matter is summed up by the author, and his conclusion is that the anophelines associated by experience in the transmission of malaria are chiefly house-haunters and night-biters. "Malarious houses" exist in which all the inhabitants suffer one after the other from malaria, and it is pointed out that, in Europe at least, such dwellings are dark, dirty, and often damp. Well-lighted, clean, and efficiently screened houses are of paramount importance in highly malarious areas, and the various lines of investigation collected in this concise review prove conclusively that the house is a factor of primary importance in the acquisition and spread of malaria.

COD-LIVER OIL AND RICKETS

A note on vitamins and bone growth which appeared in the *Journal* of November 21st provoked some criticisms on the part of Dr. Hugh Thursfield, whose letter was published in the following week's issue. Dr. Thursfield holds that the gradual disappearance of severe rickets preceded experimental work on vitamins (work to which our reviewer attributed recent advances in the prevention and cure of the disease), and that it was due mainly to improved baby-feeding and to the infant welfare movement. He further disagrees with the view that in the early years of the present century the majority of clinical workers failed to recognize the specific value of cod-liver oil in rickets, and that most writers even emphasized its disadvantages. When, with its characteristic fertility, medical specialization has begotten yet another child—the paediatric statistician—problems of this kind will perhaps be easy of solution. In the meanwhile, it is of interest to consult textbooks of the 1900–10 period as a guide to current professional opinion of the value of cod-liver oil in rickets. At least a few writers preserved, on this question, an attitude neither mainly condemnatory, as our reviewer suggested, nor frankly enthusiastic, as in Dr. Thursfield's view. It seems to us that an examination of the following comments shows authoritative opinion of the time to have been either lukewarm or non-committal or [illegible]

We will, however, leave it to our readers to form their own judgement.

Burney Yeo's well-known textbook on therapeutics (1910 edition, vol. ii, p. 542 et seq.) devotes three and a half pages to the treatment of rickets. Cod-liver oil is dismissed in five lines, raw meat pulp being described as of equal importance. In Allbutt and Rolleston's *System of Medicine* (1907, vol. iii) it is stated:

"Cod-liver oil is useful in some cases, especially when good milk and cream are not obtainable or not well borne, but it is to be regarded rather as a food than as a drug. . . . Drugs play a secondary part. As a rule far too much reliance is placed upon them, and children are drenched with cod-liver oil, iron, 'chemical food,' or lime-water often to the disturbance of digestion and the impairment of natural appetite and consequently of nutrition. Such remedies are useful and have their place; but they are by no means essential or of prime importance in most instances."

Osler and McCrae (1910, vol. i, p. 888) state:

"Cod-liver oil is most commonly used in England, but other oils such as cotton-seed oil and olive oil have been used, and apparently it makes little difference how the fat is supplied, provided it can be digested."

Cushny's *Pharmacology* (first edition, 1900, p. 705) states:

"It would seem, then, that cod-liver oil has not been shown to have any action apart from its being an easily digested food. The older attempts to explain its superiority to the other oils have not been successful."

At the opposite end of the scale may be quoted two other works. Hare's *System of Practical Therapeutics* (second edition, vol. ii, p. 236) states:

"While of little importance as compared to dietetic and hygienic management, medicine may aid in checking the progress of rickets. Cod-liver oil is the most important agent, and should not be omitted when it is tolerated by the stomach."

Fagge and Pye Smith's *Textbook of Medicine* (1901, vol. i), after mentioning that the most important treatment is dietetic, states: "Among medicines the most valuable is cod-liver oil." Other drugs referred to are steel wine, quinine, and tannic acid.

INDUSTRIAL WELFARE

The annual report of the Industrial Welfare Society for the year ended June 30th, 1931, which has just been issued,[1] is a record of steady progress in a number of directions. The main work of the society is to encourage the study among employers and others of questions affecting the welfare of all persons engaged in industry. To this end special conferences are held from time to time in various industrial centres, in addition to the annual conference, which takes place at Oxford. For instance, a conference held in the past year at Manchester discussed the question of health in industry, while another conference discussed the question of mechanization. Again, the advice of the society on matters relating to industrial welfare is in constant request by numerous industrial firms, while members of the staff of the society frequently address meetings at rotary clubs and elsewhere concerning its work. The health of the industrial worker forms a prominent feature of the society's activities, and the Advisory Medical Committee, an honorary body attached to the society, is often called upon to give expert advice on health problems raised by industrial firms. This medical committee meets regularly throughout the year, and its members give lectures on subjects relating to the promotion of health in industry. The Industrial Welfare Society has always taken a deep interest in accident prevention, and we are glad to hear that it is now going to act in close relation with the National Safety First Association, its special role being propagandist work towards reduction of accidents. The only unsatisfactory feature of the report is the financial one, which is almost inevitable under the conditions of economic disturbance now prevailing; but the deficit in the year's working is indirectly balanced by a generous gift to the endowment fund. The Duke of York, who is the president of the society, has shown his continued interest in its work by visiting a number of factories in London, by attending a conference at Nottingham, and by taking the chair at the annual general meeting last week.

THE PHOTOGRAVURE PLATES

At the Annual Representative Meeting of the British Medical Association at Eastbourne last July the Chairman of the Journal Committee, in his review of the year's work, said that the *Journal* was now better printed, better illustrated, and in every way a finer production than before. Sir Robert Bolam's opinion was endorsed by the meeting, and we may perhaps add that many readers have expressed their appreciation of the efforts made to improve the look of our pages. The change in typography was made at the end of 1930, the first issue of the New Year being printed throughout in a more legible and agreeable type than any hitherto used. This improvement in the printing of the letterpress followed hard upon a change in the method of reproducing pictures on special plates. We have had so many complimentary inquiries about these plates that a brief explanation here may be welcomed. Since November 8th, 1930, the process employed for producing special illustrated pages in the *British Medical Journal* has been that known as photogravure. This is a photo-mechanical method, based, like ordinary letterpress blockmaking, on photographic processes, but applied on an entirely different principle. Whereas an ordinary half-tone block to be printed on a letterpress machine is printed from its surface, a photogravure illustration is taken from an intaglio plate, the ink being drawn out of its depths. In a block, the black parts of the illustration are the highest parts of the block, the half-tone portions are lower, and the high lights lower still. In photogravure the printing surface is exactly reversed; here the high lights are the highest parts of the plate, the half-tones are again lower, and the blacks of the picture are still more deeply recessed. Thus in ordinary letterpress printing a sheet of paper takes an impression from an inked block by being brought more or less lightly into contact with it. But with photogravure the plate, after being inked, must have all superfluous ink removed from its highest surface (the high lights in the picture), while the ink is allowed to remain in the lower depths of the plate (the blacks and half-tones of the illustration); and in the actual printing operation very great pressure must be exerted in order to force the paper into the deepest recesses, so as to transfer the ink thence to the paper. From the foregoing it will be seen that not only does photogravure require a different kind of printing surface,

but also a different kind of printing machine. For photogravure plates, as for half-tone blocks, a "screen" is used to produce a broken surface capable of holding the ink; but in the former the screen is much less obvious, and is indeed difficult to detect without the aid of a magnifying lens. Hence minute detail is rendered with much greater accuracy—a point of considerable importance in the reproduction of scientific illustrations such as photomicrographs. Photogravure has this further advantage—that the best results are got by the use of natural-surfaced papers, thus avoiding the distracting reflections from the highly glazed coated "art" papers which are essential for printing from fine-screen half-tone blocks. Readers who have followed this account and wish to judge for themselves should compare the photogravure plate in our present issue with the art paper plate in the *Journal* of October 4th, 1930, or any earlier issue.

IMMUNIZATION AGAINST SNAKE VENOM

Once again the annual report of the Walter and Eliza Hall Institute of Research in Pathology and Medicine[1] deals at considerable length with the investigation of Australian snake venoms. Although financial stringency has compelled the Commonwealth Department of Health to withdraw its grant, rigid economies at the Institute have made it possible to continue the various researches. The cost of venom collection and of the preparation of antiserum at the Commonwealth serum laboratories is still being met, though with difficulty. An attempt was made last year to ascertain whether the serological blood relationships of some Australian snakes could be used to confirm the morphological findings in the differentiation of closely allied venomous species, and the specificity of the precipitin and complement-fixation reactions has been explored. Neither of these methods in its simple form was found to permit the differentiation of species, the precipitin tests in particular proving to be widely non-specific, especially when strong antiserums were used. The complement-fixation test proved to be rather more specific, and the results yielded were in accord with the zoological findings. Haemagglutination does not appear to be much more specific than the two previous tests, but further studies are being undertaken to determine its value more exactly. Earlier experiments upon guinea-pigs immunized with a number of venoms had suggested that active immunity in this species was less specific than the passive immunity conferred by the injection of monovalent antivenene. Groups of rabbits immunized against the venoms of the tiger snake, copperhead, and death adder respectively were found to exhibit a higher degree of non-specificity than could be explained by the action of circulating antibodies. In the attempt to explain this phenomenon it was shown that venoms closely allied to those used for immunization could function as secondary stimuli in these immune animals. It appeared doubtful, however, whether the time needed for this response was enough to account for the observed non-specific protection; it was certainly insufficient when death-adder venom was used for testing. It was finally suggested that an additional factor in immunity might be the accumulation of antibody in the tissue spaces round those cells which were peculiarly liable to attack. Another line of investigation was indicated by the fact that the Australian venomous snakes, and, to a less degree, some non-venomous ones, possess an extremely high immunity to Australian venoms, but are susceptible to the action of cobra venom. This immunity is in striking contrast with the susceptibility of mammals, and cold-bloodedness can be excluded as the prime cause of the difference. Various theories have been put forward to account for this, and it has been suggested that venom, or its constituents, are constantly, or intermittently, present in the circulating blood of these snakes. It has been made clear that they have an immunity to neurotoxin and thrombin, but no evidence of either of these substances could be found experimentally in the plasma. One hypothesis, which has not been presented before, is that the venom gains entry to the blood stream by self-inflicted bites, or by the bites of other snakes, and that a process of survival of the fittest has resulted in the development of immunity. Whatever the mechanism may be, it is clear that the most important factor in developing the immunity of snakes to their own and to allied venoms is a natural immunity of the tissues of the central nervous system, which allows them to withstand even high concentrations of venom for a long time. Since even large doses of venom cannot act as specific secondary stimuli, the antitoxin immunity of snake plasma is unlikely to be of the same nature as that developed in mammals in the course of active immunization.

TESTIMONIAL TO DR. ALFRED COX

A meeting of the executive committee of the Cox Testimonial Fund was held on November 11th. Sir Ewen Maclean presided, and there were sixteen other members present, together with the honorary secretary, Dr. E. R. Fothergill. It was decided to insure the portrait from the date of its completion, to cover all risks during its exhibition at the Royal Academy, 1932, and until it had been finally handed over to the British Medical Association. The presentation, it is hoped, will be made at one of the functions of the Centenary Meeting of the Association, to which all subscribers to the fund will receive an invitation. It was decided to send nominal rolls of subscribers to the fund up to December 1st, 1931, to the secretaries of Branches and Divisions, in order to assist them in their campaign for the success of the fund in their areas. The number of contributions received from members in the British Isles up to November 1st was 1,455, this being the result of only four weeks' appeal; and further sums are still coming in in large numbers. The Oversea Branches are conducting their appeal separately. It was decided that a presentation book should be prepared, giving the names and addresses of subscribers, and presented to Dr. Cox during the Centenary Meeting at the same time that the portrait is presented to the Association. The committee is anxious that as many members as possible should contribute to the fund, sending any sum they like, not exceeding ten shillings.

We much regret to announce the death of Sir T. Eustace Hill, who retired last year from the post of medical officer of health for the county of Durham, and from the professorship of hygiene and public health in the University of Durham College of Medicine

The First Hundred Years

NOTES ON THE HISTORY OF THE ASSOCIATION

THE British Medical Association, founded at Worcester in 1832 by Sir Charles Hastings, celebrates its centenary next July, under the Presidency of Lord Dawson of Penn. In anticipation of this landmark in professional history the Council invited Mr E. Muirhead Little, F.R.C.S., to undertake the task of annalist. We publish below the first of a series of advance extracts from the *History of the Association*, which Mr. Muirhead Little is preparing for publication at the time of the commemorative proceedings in Worcester and London.

THE MEDICAL PROFESSION IN 1832

The year 1832 was an eventful one, for besides the foundation of the Provincial Medical and Surgical Association (renamed later the British Medical Association), it saw the passing of the first Reform Bill, and the first epidemic of Asiatic cholera in Great Britain. The Anatomy Act, which put an end to body-snatching and its scandals, became law in that year; Tennyson's first volume of *Poems*, which included some of his best work, was published, and Charles Darwin, only a few days before the year began, started on that five years' voyage in the *Beagle* which led to such momentous developments in natural science. The whole lustrum 1830 to 1835 was momentous. The country had largely recovered from the economic depression following the long wars with France and her allies, and the people were full of creative and inventive energy, which manifested itself in many ways. In 1830 the first passenger railway of any practical value was opened from Liverpool to Manchester, after the Stockton and Darlington line, which was designed for mineral traffic, had proved successful some years earlier. Successful trials of the first iron steam vessels were carried out on the Thames, and London Bridge, which had stood for more than six centuries, was demolished, and its successor erected upon a different site.

The Reform agitation had not been entirely peaceful. The mob had burned Nottingham Castle and the Bishop's palace at Bristol, these riots being accompanied by loss of life. The cholera epidemic had led to the provision of cholera hospitals, some of which were not popular. In the *Annual Register* for 1832 will be found accounts of attacks on such hospitals by the mob. At Manchester the patients were removed and the contents of the building destroyed by the rioters, while at Paisley the windows of the hospital and those of the surgeons' houses and shops in the town were broken. Some cholera patients were injured by stones, and the hearse used for the dead destroyed. Rumours of resurrectionist activity had, however, something to do with this last riot. Primitive customs still lingered in England. At Carlisle Market, in April, 1832, a small farmer offered his wife for sale, with her own consent, for fifty shillings. Judging from the report of his speech, he and she were by no means uneducated, in the *Annual Register* she is described as a "sprace lively damsel." She was knocked down "for twenty shillings and a Newfoundland dog," and taken away by her purchaser, apparently not ill-pleased. In this same year was founded the first of the modern provincial English universities, that of Durham.

At this time that great octopus, London, or as Cobbett called it, the Wen, had not spread its tentacles over the country as it has done since, and it had not yet sucked much of the life blood out of the provincial towns. Such cities as Worcester, Bristol, Exeter, Norwich, Winchester, and many others had a vigorous local life, and supported consultants in medicine and surgery. Many of the landowners in the neighbourhood had their winter residences in these towns, instead of in London as in later years, and their young folks found entertainment in local assemblies. But the centripetal movement had begun, as is shown by the fact that the town house of the Lechmeres in Worcester became the residence of the founder of the Association.

The medical profession in 1832 found itself face to face with the cholera epidemic, unprepared and unarmed against it. The committee of one of the great London hospitals, with commendable enterprise and foresight, sent one of its physicians with a prosector to study it on its first appearance at, and near, Newcastle-on-Tyne. The physician's report revealed the terrible mortality in certain villages, and put on record the symptoms and post-mortem appearances, but was not able to claim any success in treatment. Indeed, the *Annual Register* was not unduly pessimistic when it stated that "the cholera left medical men as it had found them, confirmed in most opposite opinions, or in total ignorance as to its nature, its cure, and the causes of its origin, if endemic, or the mode of transmission if it were infectious. In Great Britain, as elsewhere, it fixed its residence among the most needy and squalid classes of the community." The sciences of epidemiology and public health did not, and in the absence of statistical information could not, exist. Until the passing of the Registration Act of 1836 there were no national statistics from which trustworthy conclusions could be drawn, although a beginning had been made with the decennial census of population in 1801.

In the medical profession, as in industry and invention generally, the sap was stirring, but there was no means by which it could make its influence felt. The profession was not organized, not even defined, for there was no hard-and-fast line drawn between the qualified and unqualified practitioner, nor was there any simple criterion by which the members of the public might distinguish between the reputable practitioner and the quack. Twenty-six years were to pass before the Medical Act of 1858 in some measure provided a remedy for this state of affairs. But notwithstanding this want of organization and definite status, it is a mistake to assume, as more than one writer has done, that there was no body of opinion and feeling which animated practitioners before the passing of the Medical Act of 1858, or which inspired a large number of practitioners with a consciousness of professional brotherhood. From the moment in 1823, when the *Lancet* constituted itself the voice of the medical profession, it became evident that there was a body of men who felt that they belonged to a great profession. They were split up into groups—some of which mistrusted or were jealous of others—but, ill-defined as its units might be, the profession of medicine existed.

That this conclusion is sound may be inferred from the terms of the address delivered by Charles Hastings on the occasion of the first meeting of the Association in 1832. He and his colleagues used the phrase "medical profession" frequently, and he characterized medical liberal profession. Evidently the creation had

and for twenty-six more years it continued to flourish without any lawful regulation of its members outside the jurisdictions of some of the corporations. Yet it is not to be wondered at that writers, looking back from a period half a century later, should have doubted the existence of a medical profession in the days of their grandfathers. With characteristic British indifference to definition, regulation, and exact order, the nation had allowed a chaotic state of things to exist too long.

MEDICAL CORPORATIONS IN 1832

The first attempt to regulate surgical practice in the London district since the days of Charles I is represented by an Act of George II. The Royal College of Physicians of London had long had a monopoly of the practice of physic in London and seven miles round. In 1815 the London Society of Apothecaries had succeeded in getting an Act of Parliament passed which restricted the practice of pharmacy to its licentiates throughout England, and at the same time entitled it to grant licences to practise physic. In Scotland the Edinburgh College enjoyed privileges which restricted practice in certain counties to its members, and the Glasgow Faculty of Physicians and Surgeons had similar rights in counties adjacent to Glasgow. As Mr. Walter Rivington wrote: "Within these bounds no one was to exercise the art of medicine without a testimonial of a famous university in which medicine was taught, nor could anyone practise as a surgeon unless he was a member of the Glasgow Faculty." In Ireland the King's and Queen's College of Physicians enjoyed privileges, conferred in 1692, restricting the practice of physic to their licensees all over Ireland. The College of Surgeons in Ireland does not appear to have had similar jurisdiction. The ancient English and Scottish universities stood somewhat aloof from the ordinary practice of medicine and surgery. Their graduates had the right to practise throughout their respective kingdoms, but the universities exercised no disciplinary control over them, and had no powers for the suppression of unqualified practice.

Any attempt to estimate the amount of unqualified practice in England before 1832, or even 1858, is attended with great difficulties. Until the *Medical Directory* for England and Wales appeared in 1846 there had been no list of the great body of general practitioners except for an enterprising publication of which only three issues were made. These referred respectively to the years 1779, 1780, and 1783. This publication was called the "Medical Register," but, unlike the present official *Medical Register*, it was published without authority. Copies of it are now very rare. From the issue for 1783 we learn that sixty years before the foundation of the Association there were 778 members of the Corporation of Surgeons, and 301 of the Society of Apothecaries of all ranks—a total of 1,079. At the same time the College of Physicians had only 114 Fellows, Candidates, and Licentiates. The reputed surgeons and apothecaries in England and Wales (excluding London) amounted to 1,573, from which it would appear that only about two general practitioners out of three had any qualifications. At the same time there were 337 physicians in the provinces, of whom very few had any connexion with the London College of Physicians, most of them holding Scottish or Continental doctors' diplomas None of these appear to have held Irish degrees. The Apothecaries Act of 1815 no doubt wrought a great change, so that by 1832 probably the proportion of unqualified practitioners was much reduced. Nevertheless, in 1853 the *Medical Times and Gazette* estimated the number of unqualified practitioners at double that of the qualified. It was stated in the House of Commons in 1841 that out of 1,830 candidates for medical office under the Poor Law, 320 had never been examined in surgery, 323 never examined in medicine, and 233 had not undergone any professional examination whatever. Yet these persons were all eligible for medical office under the Poor Law. The 1841 census gave 33,339 persons as practising one or more branches of medicine. The medical directories of 1853 (the nearest in date available) show that only 11,308 were then qualified.

From this short survey of the powers of the corporations in 1832, it appears that all over England, except in the environs of the capital, no attempt was made to regulate the practice of medicine and surgery, apart from the Apothecaries Act of 1815, which provided for the sufficient examination of candidates for the Licence, and which, in the words quoted by Walter Rivington in 1879, "created a body of qualified general practitioners in England and Wales, who were entirely independent of the College of Physicians and Surgeons, and were entitled to practise medicine not merely by sufferance, but by law."[1] Thus did a City company step into the breach, and take up a duty which might rightfully long before have been assumed by the Royal College of Physicians of London which, unfortunately, had preferred to remain aloof in its academic majesty, and to take no interest in the practice of physic in the metropolitan area was infringed. But even its limited power of regulation practice had fallen into desuetude. The last prosecution undertaken by the College was that of Dr. Edmund Harrison in 1828. The practice was found to be supine and although the faculty of physic includes surgery College was non-suited and had to pay costs.

The best instruction in anatomy, physiology, medicine and surgery had, up to this time, been provided by the so-called private medical schools, unconnected with hospitals. Such were the Great Windmill Street school of the Hunters and Sir Charles Bell, that of Brookes's or Blenheim Street, the Webb Street School, Carpue's or the Dean Street school, and Dermott's, the Gerrard Street, Little Windmill Street school. All these once flourishing if commercial, institutions were gradually squeezed out of existence by the refusal of the College of Surgeons to accept their certificates, and most of them were closed by the year 1832, although one or two lingered on for a good many years later.[2] Their success had in part been due to the better bargains which they were able to make with the "resurrection men" as compared with the official hospital schools. The Anatomy Act of 1832 nullified this advantage.

A hundred years ago the average medical practitioner was a man of little culture or general education. The graduates of Oxford and Cambridge and of the Scottish universities were probably as well educated as the members of the learned professions of the Church and the Law, at least in those cases in which the degrees had not been granted without due academical training, but the rank and file of the profession had received its training through the system of apprenticeship. Whatever the advantages of this system may have been, it is undeniable that it involved at the best the too early termination of the general education of the lads who, in order to get qualified by the time they reached the age of 21, must have left school at the age of 15 or 16. At its worst, if the master neglected his duties, or the pupil was apt and cared little to learn, the period of apprenticeship too often represented so much precious time wasted

Contemporary portraits of the medical students who were "walking the hospitals" after leaving the care of their masters are not flattering to our professional self-respect. *The Pickwick Papers* began to appear in

[1] Carmichael Prize Essay, 1879, p. 24.
[2] *British Medical Journal*, 1895, ii, 1388, The Rise and Fall of the Private Medical Schools in London.

1836, and everybody knows what kind of figures were cut by Bob Sawyer and Benjamin Allen. No doubt these were not meant to be taken as serious portraits, but were painted in a spirit of light-hearted caricature, yet there was a substantial basis of sober truth in their regrettable lineaments. Nor do they stand alone. Thackeray, writing a dozen years later in *Pendennis* in a more serious vein, had made the portrait of Huxter no more attractive than those of Sawyer and Allen. Albert Smith, himself a member of the profession, did nothing in his novels to improve the reputation of the student. In the second volume of *Punch* (February 12th, 1842) one of a set of valentines is addressed to The Medical Student. The drawing was by John Leech and the verses by W. H. Wills, and both confirm the descriptions given by Albert Smith. Even in the pages of a medical journal, which might be expected to avoid fouling its own nest, most unfavourable descriptions are given of the manners and customs of London medical students. These anonymous articles in the *Medical Times* are said to have been written by Albert Smith. The conclusion seems inevitable that there must have been a large basis of fact under these writers' attacks on medical students, but there were doubtless many earnest workers who were neither dissipated nor dirty (Dickens and Thackeray both insisted on the lack of personal cleanliness in their medical students), and who became highly respected members of society; and it needed a good many men of the quality of Sir Charles Hastings, and a good many years of improved behaviour, to live down this scandal.

SHEFFIELD MEDICAL DINNER

PRESENTATION TO PROFESSOR A. J. HALL

The annual medical dinner at Sheffield was held on November 26th at the Royal Victoria Hotel. Professor Arthur J. Hall was the guest of honour, and the unusually large attendance of nearly two hundred gave evidence of the respect and affection in which he is held.

Dr. A. E. BARNES, in proposing the toast of "Our Guest," spoke first of what Hall had done in building up the Medical School. Coming to Sheffield from Bart's in 1889 as assistant demonstrator in physiology in the old medical school in Surrey Street, he became sole lecturer in physiology three years later. It was through his energy that the Favell Physiological Laboratory was established in 1895. Leaving physiology in 1898, Hall took on the department of pathology, housed at that time in some old shops in West Street. Enthusiasm, however, made up for lack of equipment, and here was commenced that pathological service which had been made available for all local practitioners. Hall took an active part in the steps which led to the founding of Sheffield University, which was opened by King Edward in 1905. Here he organized the laboratory for clinical pathology, and was, some years later, appointed to the chair of medicine. It was to Hall that the Sheffield Hospital Staffs Club owed its formation, leading to the almost complete disappearance of the friction and ill feeling between the leading members of the profession which was so marked in those earlier days. In recent years his scientific work on encephalitis was well known, and he had done important work on silicosis for the Home Office. Amid all these activities his intense interest in the welfare of his students has been unaltered.

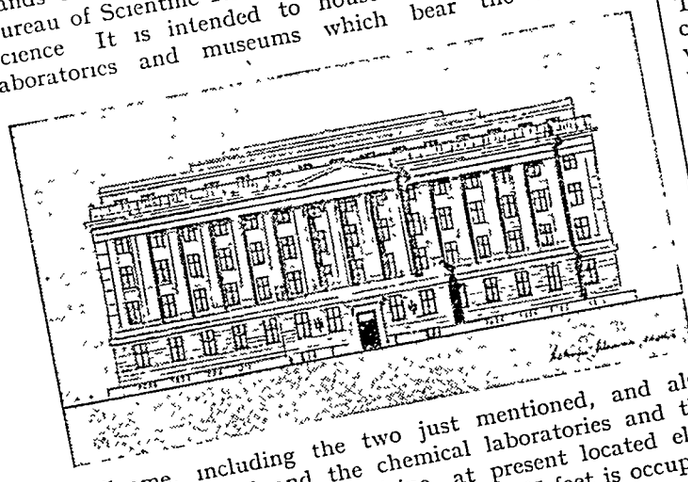
Dr. HERBERT HALLAM, speaking as an old student of Professor Hall's, and also as a representative of the family practitioners of Sheffield, said that Professor Hall was himself the son of a much-loved family doctor in Sheffield. His organizing ability, his genius for finding common-sense solutions of difficult problems, his tolerance, his delicate humour irradiating many otherwise dull scientific proceedings, his freedom from pomposity and "side"—these were some of the things which had endeared their guest to them, and earned their grateful appreciation.

Dr. ARCHIBALD YOUNG claimed to be Professor Hall's oldest student in Sheffield. He could recall their guest in 1889 coming to a medical school that was almost dying—out of date, with no spirit of progress, and no proper equipment. As students, they found in Hall a born teacher, a man of ideas, who was able to infuse into his students a real interest in work, and a man who was able to get things done. He reorganized their classes, and obtained proper equipment. He rescued that dying medical school, and his "epic fight with circumstances" saved the school at the critical moment. "All through its development he has been the force behind it." In view of all that Hall had done in Sheffield it was felt that the year of his retirement from the official positions of senior physician at the Royal Hospital and professor of medicine in the University ought not to pass without some fitting expression of the appreciation of the members of the profession. It was his pleasant duty to present to Professor Hall a cheque for £573, and a book containing the names of all who had contributed. The presentation was made on behalf of his old students and colleagues at the hospital and university, as well as all the practitioners in Sheffield and district.

Professor ARTHUR J. HALL expressed his deep sense of appreciation of the honour done him as the guest of such a gathering, and also for the presentation made by Dr. Young. In a felicitous speech he contrasted medical life forty years and more ago with present-day conditions. He remembered as a boy having to help to "make or mar" many pills, plasters, and ointments for his father's patients; for in those days doctors not only had to dispense their own medicines, but to make them. Practically the doctor's only piece of apparatus was the stethoscope, and it was used most commonly without removal of the patient's clothes. The clinical thermometer was just coming into use, but was still regarded by most as a new and unnecessary fad. They had to concentrate on what they had—the pulse and the tongue. All the diseases of the abdomen had to be diagnosed from the condition of the tongue. The peritoneum was, in a very real sense, "a closed cavity." Medicine has progressed perhaps more than any other science since those days. Diphtheria was a bugbear at that time; there was so often the horrible question, whether or not to do tracheotomy, and, whatever the decision, it was too often followed by the loss, not only of the patient, but of the family from the practice. In the realm of prevention of disease, the prevention of typhoid fever in the great war, by inoculation, deserved to rank as one of the greatest achievements in medicine. The modern treatment of myxoedema, of diabetes, of pernicious anaemia—these, as well as our knowledge of vitamins, were, every one of them, advances brought about by accurate scientific investigations. The same methods made possible progress just as immense in the future. The manufacturing pharmacist and the mechanization of medicine had both come, and come to stay. Yet in spite of all this, just as the old rudder and the man at the helm were necessary to the modern battleship, so the physician, with his ear and his hand, must always be a primary necessity in medical practice. In conclusion, Professor Hall called attention to the fact that at the present time both the senior physician and the senior surgeon at the senior institution in Sheffield were old students of the Sheffield Medical School, and asked that the profession would extend to his successor, Professor A. E. Naish, the same support that he had received.

Dr. J. MACKINNON, proposing the toast of "The Medical Faculty," referred to the increasing influence exerted by the State in medical affairs, and said the time was coming when the medical faculties of our universities might find it wise to take a larger share in the medico-political work of the profession. Professor GRAHAM SIMPSON, in responding, referred to the loss Sheffield had just sustained by the death of Professor Douglas, the dean of the Medical Faculty. This, the largest medical dinner he had known in Sheffield, was a great occasion for the profession.

Dr. E. F. SKINNER, in proposing the toast of "The Chairman," said that they had every confidence that Professor Naish would maintain the high traditions left



by his predecessor: he was a clinician conversant with all modern methods, and held the position of president this year of the Yorkshire Branch of the British Medical Association. Professor A. E. NAISH acknowledged the honour of presiding at that historic gathering, and said that their best appreciation of what Hall had done for the Sheffield Medical School would be to continue to press forward in the same progressive spirit.

The Medical Dinner Committee is to be congratulated on the way in which this very successful gathering was organized. The heaviest work fell on its secretary, Dr. R. E. Pleasance, Dr. E. F. Paige having also taken a prominent share, as representing the Women's Medical Federation in Sheffield.

WELLCOME RESEARCH INSTITUTION

CORNER-STONE OF NEW BUILDING LAID BY LORD MOYNIHAN

The corner-stone of the Wellcome Research Institution in London was laid on November 25th by Lord Moynihan, President of the Royal College of Surgeons. This handsome building, whose main frontage is to Euston Road, stands on the site previously occupied by the Wellcome Bureau of Scientific Research and the Museum of Medical Science. It is intended to house the various research laboratories and museums which bear the name of

Wellcome, including the two just mentioned, and also the physiological and the chemical laboratories and the Museum of Historical Medicine, at present located elsewhere. A space measuring 225 feet by 135 feet is occupied by the new erection, and the façade, with a colonnade of twelve fluted Ionic columns, masking the second, third, and fourth floors, will be a noteworthy piece of London architecture to greet the visitor on his arrival at Euston station. The building is being furnished and equipped in the most modern fashion, and, with the exception of some Italian marble, the whole of the materials used are Empire products. It was stated that 89,000 tiles are being used for the construction of the floors, and 220 tons of marble, principally for wall linings. One of the features will be a lecture hall with a ceiling treated with sound-absorbing felt.

The stone-laying ceremony took place in the presence of a large company, including representatives of several foreign legations, High Commissioners for the Dominions, representatives of various bodies having imperial interests, of public health authorities, and of London University, and members of the medical profession. A bronze casket, containing historical records of the Wellcome Research Laboratory and museums, was inserted in the corner-stone, and a silver trowel was presented to Lord Moynihan by the architect, Mr Septimus Warwick.

Dr HENRY S WELLCOME said that the building had long been projected by him, and he had been fortunate in finding his ideas realized by Mr. Septimus Warwick, the architect, whose notions of the architectural embodiment had corresponded to his own. He had a strong belief in the inspiring influence of symmetrical and graceful architecture, and he had found that an artistic environment was not incompatible with scientific research, but even stimulated and facilitated the solution of problems. He added that a special tribute should be paid to Mr. Warwick for his success in creating this building, and great credit was also due to the builders, who were completing the work, already well advanced, within twelve months of obtaining possession of the site.

LORD MOYNIHAN'S ADDRESS

LORD MOYNIHAN, after laying the corner-stone, said: "To-day we lay the corner-stone to a life's work." Dr. Wellcome, for nearly forty years, had so directed his most earnest thoughts, and had so bestowed his lavish gifts, as to create a great instrument for medical research and to found a museum illustrating the significant events in medical history. His earlier labours were engaged in many directions. It was in 1894 that he founded laboratories for physiological research, to be followed two years later by those for chemical research. When Kitchener recaptured the Sudan, Dr. Wellcome, one of the first civilians to visit that country, realized by personal contact with misery and illness in many forms that there lay an unequalled opportunity for service. Little was then known of many of the diseases which for long had ravaged the districts brought under British rule. In 1899 Kitchener opened laboratories in Khartum built and endowed by Dr. Wellcome for the investigation of tropical diseases. The late Sir Andrew Balfour was the first director, and continued his work for twelve years. With this institute was associated a floating laboratory, towed to all waterways of the Nile, affording opportunity for the collection of specimens, and for observation and inquiry in an otherwise inaccessible.

Dr. Wellcome's activities continued also in this country. In 1913 he established the Bureau for Scientific Research and the Historical Medical Museum, in the following year the Museum of Medical Science, and in 1920 the Entomological Field Laboratory. All these institutions, or many of them, suffered, however, under one great disadvantage, which all research students would appreciate at once; they were separate from one another, giving no opportunity for that hour-to-hour consultation which was one of the great advantages of having collective research under one roof. But now that was being altered. Under this one roof the following subjects were to be studied: medical zoology, parasitology, entomology, tropical medicine and hygiene; there would be physiological and chemical laboratories, the historical museum, and a museum of modern medicine—a very formidable and impressive list. Dr. Wellcome's activities, however, had not been confined to this country, for the speaker had lately been reading an account of the proceedings whereby he had given great help towards the foundation of the Gorgas Memorial Laboratory, near the Panama Canal.

One of the conspicuous features of Dr. Wellcome's lifework, the speaker proceeded, had been at once its relevance and its opportunism. In all his investigations of tropical diseases he began in an almost virgin country, and the harvest gathered had been such that not only had many lives been spared and much suffering saved, but vast tracts of country had, for the first time, been made fit for human habitation. At home the great need of medicine to-day was in the direction of increasing the opportunities for medical research, and not less in the opportunities for creating those competent to undertake medical research. Physical observation alone, from the time of Hippocrates through Sydenham, Addison, and James Mackenzie, had revealed many secrets which had been long hidden in connexion with diseases that lay within the orbit of pure investigation, and the conquests of mere observation had been innumerable and of a value beyond all reckoning. Upon it a virile and beneficent art had been built, to the infinite advantage of mankind. It was within living memory that this most exquisite art had found its opportunities extended and its methods affected by the encouragement and adoption of researches which were seeking to change a practical art into an

applied science Difficulties, of course, had been found all along the way, but experiment in medicine was for ever inevitable

'As a result of experiment in medicine," Lord Moynihan said in conclusion, "we are happily gradually replacing anatomy by physiology, and if disease is, in many respects, merely altered function, then we are about to create a science new to humans, of comparative function in health and in disease But experiment has done even more for us than that I think it has strengthened the arm of medicine, and it has made the tests more severe for the acceptance of evidence which has been derived by the methods of observation Medicine depends of course, not only for its present stability, but for its future advance, upon a large number of ancillary sciences Those sciences are to be studied in this building The effect, therefore, on medicine will be considerable but I hope something better even than that will come out of the work done in this institution and similar institutions, that is to create in the minds of the leaders of the profession what my friend Sir Walter Fletcher would like to call 'the religion of research' I hope the date is not far distant when those who are to serve upon the teaching staffs of hospitals throughout this country will be permeated by the religion of research, and in time to come, all members of the teaching staffs will themselves have undergone, in institutions similar to this, a discipline of research To-day, in your name I would like to offer our homage to the man who has made this institution possible, and by his constant thought and by his most lavish generosity has done as much, I think as any man has ever done in this country to make it possible for those who work within our profession to advance both the science and the art of medicine"

Following Lord Moynihan's address, Dr WELLCOME added a few further words, saying how much he was honoured in having had associated with him so many brilliant young men who had entered with zest into these enterprises Much of the credit that had been given to him belonged to others, and those not only the directors of the various departments of the institution, but the members of their staffs

England and Wales

Liverpool Medical Institution

A special general meeting of the Liverpool Medical Institution was held on November 19th when honorary membership was conferred by the president, Professor W Blair Bell, on Lord Dawson of Penn Emeritus Professor Archibald Donald, and Sir Robert Jones, who were formally introduced by Professor John Hay, Professor H Leith Murray, and Mr K W Monsarrat respectively Professor Donald replied on behalf of the new honorary members The annual dinner of the institution was held at the Adelphi Hotel the same evening, when the guests included in addition to the new honorary members, the Lord Mayor of Liverpool, Vice Chancellor Dr H J Hetherington, Canon T A E Davey, Professor W Fletcher Shaw, Professor R W Johnstone, and others Lord Dawson, proposing the toast of 'The Institution, spoke of the great advantages of a medical society, and expressed the wish that the influence of such societies were more readily recognized by the public There was no place like a medical society for giving the truth a free road and falsehood the go by In responding to the toast, the president said that they had the settled pride in the institution that was born of ancient tradition They eschewed all that was not directly connected with their art and science, and lived in peace and concord, untouched by medical or national political crises, unruffled by religious differences The institution was one of the greatest post graduate schools in the country, with an average weekly attendance of over seventy members This year the final year students have been invited to attend the meetings, to hear their teachers taught, and the invitation had been greatly appreciated Proposing the toast of "The City and University of Liverpool" Professor Fletcher Shaw said that in the Liverpool Medical Institution they had one of the finest of its kind in the Kingdom, and if the wealthy business men could be persuaded how important was the interchange of ideas between medical men, and how important it was for that interchange to have worthy buildings, he was certain such institutions would be found in every big medical centre The Lord Mayor and Vice Chancellor Hetherington responded Professor R E Kelly proposed the health of the guests, to which toast Sir Robert Jones and Professor R W Johnstone responded

The London Hospital: New Cardiac Department

The new heart department at the London Hospital was opened on November 25th It occupies a set of rooms comprising a spacious and comfortable waiting hall for out patients, rooms for consultation, electrocardiography, and orthodiagraphy as well as laboratories, dark rooms, offices, and dressing rooms The department was constituted in 1911, and was the first complete cardiac department of its kind in any hospital in the world For its endowment Mackenzie, founder and first physician in charge, was able to obtain £10 000 as a gift from the trustees of James Paterson In 1913 the department was reconstituted, but on the outbreak of war the staff dispersed and it was closed It was reopened in 1920, with Dr John Parkinson, who had been Mackenzie's chief assistant, as physician in charge but the inadequate and temporary nature of the accommodation hindered any real progress During a period of two years the East End Tradesmen's Association raised on its behalf a sum of £4,300 With this, £1 430 from the Paterson bequest and a donation of £500 from the Queen, the new department has been housed in premises worthy of its founder The opening ceremony was performed by Mrs C E W Charrington Sir H W Gorchen briefly recounted the department's history In speaking to a vote of thanks, Dr John Parkinson said that the new building was admirably adapted to further the study and treatment of heart affections, and the staff realized its indebtedness to the East End Tradesmen's Association The equipment included the most modern instruments for studying heart affections and estimating the effects of treatment Those who worked in this department were actuated, said Dr Parkinson, first of all by sympathy with the sick, secondly, by a natural desire to teach the members of the profession in the future how best to relieve their patients' ills, and, thirdly, by the feeling of duty to add something to the great tradition of knowledge which had been handed down to them The main consideration of medicine as a progressive science was ever in the mind of the late chairman (Lord Knutsford) who was much in their thoughts that day and it was exceedingly well exemplified in the career of their chief, James Mackenzie

Pathological Research at Leeds

In the annual report of the department of pathology and bacteriology of Leeds University Professor Matthew J Stewart and J W McLeod describe the various lines of investigation which were followed during 1930 The heavy and increasing strain of routine pathological examinations is now threatening to interfere seriously with the educational side of the department, as well as with research It is strongly urged that the time has come for the creation of a new post of resident pathologist,

this will also enable urgent examinations to be conducted at times when the regular staff are not on duty. Research work in progress includes an attempt to define the processes concerned in normal gastric functioning; the effects of asbestos dust on the pulmonary tissues; the precise nature of the pigment involved in the direct van den Bergh reaction; and the etiology of the common cold, with special reference to the mouse-pathogenic bacteria commonly found in the upper respiratory tract. In the bacteriological laboratories there has been a notable increase in the amount of teaching work due to the appearance of candidates for the honours B.Sc. in bacteriology. In an appendix to the report Professor R. D. Passey summarizes the work that has been carried on, under his direction, in connexion with experimental pathology and cancer research.

Scotland

Maternal Mortality in Scotland

At a meeting of the Scottish National Health Visitors Association in Glasgow, on November 21st, Professor J. M. Munro Kerr, in an address on "A national maternity service," said that if the problem of maternal mortality and morbidity was to be solved it required the co-operation of all the agencies concerned with maternal and infant welfare under one centralized scheme. This would include general practitioners, obstetric specialists, medical officers of health, midwives, health visitors, mother helps, local health committees, and the Department of Health. He thought that it would be opportune to promote such a scheme at a time of financial stress, when economy had to be considered. A maternity service did not necessarily involve much immediate capital expenditure, but it should be designed with wisdom and forethought. Efficient schemes were already in operation in the East End of London, in Dublin, Sweden, and Holland. He advocated an increase in hospital accommodation and in nursing homes for maternity cases, with powers to local authorities to remove to them such cases as appeared necessary, and extended training in maternity courses.

Teaching Facilities in Municipal Hospitals

A committee of the Edinburgh Town Council, along with representatives of the University, the Royal Infirmary, and the Royal Colleges, has been considering the question of teaching facilities available at the municipal hospitals of the city, and has drawn up a report on the subject. It is pointed out that one of the effects of the Local Government (Scotland) Act, 1929, was to break down the distinction that formerly existed between preventive and curative medicine, and that the Act authorized public health authorities to establish and maintain general hospitals, where necessary, for the treatment of sick persons. Provision was also made whereby persons who were sick might receive hospital treatment without being characterized as paupers. These provisions, however, were permissive and not mandatory. The Act provided, further, that the town council might submit a scheme to the Department of Health for the extension of hospital facilities, provided that steps were taken to secure full co-operation with every available hospital, university, or medical school within, or serving in, the area of the council. The committee of the town council is of opinion that the adoption of a co-ordinated teaching scheme between the corporation, the medical school, and the voluntary hospitals would be to the advantage of all concerned.

Proposed Edinburgh Health Exhibition

Arrangements are being made for holding a health exhibition in January, 1932, in the Waverley Market, Edinburgh, in aid of the extension appeal fund for the Royal Infirmary of Edinburgh. The honorary organizer of the exhibition is Dr. William Robertson, formerly medical officer of health for Edinburgh, who has been concerned with similar previous exhibitions in that city. It is proposed to show the usual exhibits of hygienic bakery, manufacture of sweets, laundry processes, the use of gas for domestic purposes, etc. It is also intended to have an exhibit illustrating the evolution of the hospital bed, also a collection of surgical relics associated with Lord Lister, and demonstrations of hospital dietetics and ante-natal work. Provision will also be made for talks on health subjects and for displays of physical exercises.

Presentation to Medical Practitioner

At a public meeting, held in the Miners' Welfare Institute, Newcraighall, Midlothian, on November 23rd, a presentation was made to Dr. John H. Balfour in recognition of fifty years' medical service in the district. The chairman, Mr. Robert Ramsay, said that Dr. Balfour had succeeded his father and brother, so that his family had practised medicine in this village and district for seventy-eight years. Dr. Balfour had always interested himself in the social well-being of the community, and Mrs. Balfour had always taken a prominent part in promoting social welfare. Dr. Balfour, in reply, expressed the hope that, although he had conducted medical practice for fifty years in the district, he would be able to continue work for a long time to come.

Ireland

Vital Statistics for Northern Ireland

During the quarter ending September 30th, 6,456 births were registered in Northern Ireland, representing an annual birth rate of 20.7 per 1,000 of the estimated population. This rate is 0.2 below that for the corresponding quarter of last year, and 1.6 below the average rate for the third quarters of the ten years 1921–30. In the Irish Free State the number of births registered during the same period was 14,405, or an annual rate of 19.5, compared with rates of 16.0 and 18.6 for England and Wales and Scotland respectively. Deaths registered during the quarter numbered 3,736, or 12.0 per 1,000. Of this number, 362, or 9.7 per cent., were of infants under 1 year, the infant mortality being equivalent to 56.1 in every 1,000 births registered. As in the previous quarter, deaths from the principal epidemic diseases and from tuberculosis show, on the whole, a noteworthy decrease when compared with the average number of deaths from these causes in the third quarters of the five preceding years, but deaths from cancer continue to increase, 377 cases being reported, or an annual rate of 1.21 per 1,000. According to the returns made by registrars, the number of successful primary vaccinations registered in Northern Ireland during the quarter was 6,173.

Tuberculosis in Belfast

In his annual report for 1930, Dr. Andrew Trimble, chief tuberculosis officer for the city and borough of Belfast, remarks that a study during the last seven years of the relative numbers of women and men found to be tuberculous at their first examination reveals a diminution among the female sex. Thus, for every 100 men found to be suffering from tuberculosis in 1916, there were 135 women, but the comparable figure in 1930 [illegible]

women was only 109. This is in accordance with the almost universal experience that, as living conditions improve, the tuberculosis death rate among women approaches that among men, or is actually less. This stage has not yet been reached in Belfast, where the female deaths from tuberculosis are still higher than the male, contrary to the general experience in Great Britain and the United States. In addition to the quarterly reports of medical practitioners undertaking domiciliary treatment of tuberculosis, a special re-examination of these patients is made at regular intervals by the medical staff of the Belfast tuberculosis institutes. The condition of these patients re-examined during the year under review indicates the highly satisfactory results accomplished despite the disabilities due to overcrowding, inadequate housing, and unemployment. Dr. Trimble adds that much more might be accomplished if the social conditions were what they might be, if the importance of attention to early symptoms was realized, and if the patients were more disposed to rest in the early stages. He believes that spitting in streets and public conveyances is on the increase, and he urges the necessity of dealing more rigorously with this offensive habit. In view of the fact that albumin is rarely absent from sputum containing tubercle bacilli, he suggests that its presence, even when tubercle bacilli cannot be found at first, should be regarded as a significant indication for frequent re-examination of the sputum, in order to avoid the risk of missing the organisms when present intermittently. With regard to the condition of children of tuberculous mothers he remarks that if, instead of considering the percentage death rate over a period of years, the infantile mortality rate—that is, the death rate of children under the age of 12 months—is studied, it is found that in Belfast the children born of tuberculous mothers died at the rate of 93 per 1,000, as compared with an average in the general population of 102 per 1,000. This somewhat unexpected result agrees with the observations of the tuberculosis officers of Lancashire and Leeds, and is attributable probably to the supervision of the visiting nurses in the homes of tuberculous mothers, with the insistence on fresh air, cleanliness, and suitable feeding. While commending the commodious and well-built schools that are now being erected by the education authority, Dr. Trimble suggests that if they were constructed on a plan which would render them easily convertible into schools of the open-air type, generously provided with facilities for personal cleanliness and sanitary accommodation, they would go far to foster and protect the health of the school children. He emphasizes the importance of increasing the number of homes for children suffering from the non-pulmonary forms of tuberculosis, especially of the bones, and also of ensuring the supply of milk which is free from infective organisms.

Queen's Institute of District Nursing

At a meeting presided over by the Rt. Hon. H. M. Pollock, M.P., of the Executive Committee of the Queen's Institute of District Nursing in Northern Ireland, the honorary secretary (Major C. Blakiston-Houston, D.L., M.P.) intimated that Dr. Foster Coates had been appointed by the Ulster Branch of the British Medical Association as representative on the Executive Committee in place of the late Dr. R. W. Leslie. He also announced that through the efforts of the Marchioness of Londonderry, and the kindness of friends, the "Lady Londonderry Nursing Scheme" had been inaugurated to assist in providing Queen's nurses for many poor and scattered areas in Northern Ireland where there was no resident nurse. The scheme will be run on the same lines as the "Lady Dudley Scheme" at present in operation in the West of Ireland. Two new district nursing associations have already been formed under the scheme this winter, and efforts are being made to establish others in necessitous areas. A satisfactory financial statement was submitted. In spite of many difficulties the garden scheme for the nurses' pension fund has met with considerable success in Northern Ireland, and many promises of continued support have been received from owners of private gardens. Five nurses have completed their district training as Queen's nurses at the Home, Botanic Avenue, and have passed the qualifying examination.

Correspondence

WINTERING IN ENGLAND

SIR,—Many persons who have been accustomed to go abroad for reasons of health are at the present time, from obvious causes, unable or unwilling to do so. The limitation of choice has, however, its compensations, for the British Islands are endowed with a large number of natural winter resorts. Their wide extent, variety, and great medical value, particularly on the south and west coasts, are, we think, too little recognized.

More precise and authoritative information on the character and value of the home resorts in the winter months seems therefore desirable, and a medical statement on the winter health resorts of the British Islands is accordingly being prepared.

We cordially invite all members of the medical profession who are interested in this matter to a meeting at the Institute of Hygiene, 28, Portland Place, on Wednesday, December 9th, at 5 p.m., to receive and consider this statement with a view to publication.—We are, etc.,

MICROCYTIC ANAEMIA

SIR,—I am very glad to give Dr. Eve my reasons for adopting the term "chronic microtic anaemia" for the group of simple achlorhydric and allied anaemias, as space did not permit this in my paper. I shall give them as briefly as possible, as I hope to discuss the classification of anaemia and the variations in the size of the red cells more fully on another occasion.

Simple achlorhydric and allied anaemias are described as *microcytic* anaemia for the simple reason that the cells are smaller than normal. The mean diameter of the red cells (normal value 7.23 microns) was measured from Price-Jones curves in a number of my cases, and the results were 6.6, 6.9, 7.0, 7.02, 7.18, 7.26, and 7.8 microns. The last was an atypical case of a patient, aged 70, diagnosed by Dr. Ryle as a transitional case with features of simple and pernicious achlorhydric anaemia. In six other cases where a Price-Jones curve was done it was described as normal in two, shifted to the left in three, and in the sixth the mean diameter was slightly raised. In a further two cases the mean diameter of the red cells was estimated by halometry as 7.3 and 7.4 microns respectively (normal 7.4 to 7.6). Quite frankly I must state my opinion that the halometer is an ingenious but unreliable toy, which is of no value in the science or the practice of medicine. Dr. Eve must bring more valid evidence to

the discussion than the results of halometry. The only satisfactory way to study the diameter of the red cells is by the Price-Jones curve. This affords an accurate measurement of the mean diameter, and, even more important, it demonstrates the variation in size of the red cells and the presence of abnormal microcytes or megalocytes.

American practice is to measure the volume of the red cells by some modification of the haematocrit technique. If we are to rely on a mean value, the volume is preferable to the diameter, for the volume varies as the cube of the variations in diameter, and any differences are so much more easily appreciated. Moreover, when we speak of the size of an object, we refer to its total bulk and not merely to its diameter. The normal mean corpuscular volume is 75 to 97 cubic microns (M. M. Wintrobe, *Amer. Journ. Clin. Path.*, 1931, i, 147). Dr. Wintrobe, in a personal communication, informs me that a typical value for the mean corpuscular volume in simple achlorhydric anaemia is 59 cubic microns. T. R. Waugh (*Arch. Int. Med.*, 1931, xlvii, 71) says that figures for the average volume of corpuscles from 60 to 70 cubic microns are common. W. P. Murphy and G. Fitzhugh (*Arch. Int. Med.*, 1930, xlvi, 440) give values of 70, 75, 75, and 90 cubic microns in four cases of chronic chlorosis, all of which had 63 per cent. or more of haemoglobin. Experiments I have made confirm this low corpuscular volume.

It is obvious from all these data that in simple achlorhydric anaemia the size of the red cells is normal or diminished. As a general rule, which is not free from exceptions, the deeper the anaemia the smaller the red cell. These anaemias are therefore well named "microcytic," in contrast to pernicious and allied anaemias in which the size of the red cell is increased, and the deeper the anaemia the larger the red cell.

While I am discussing the vexed question of terminology, may I also be permitted to point to the ambiguity which has crept into the use of the word "hypochromic"? It is sometimes used to mean anaemia of low colour index, and at other times hypobilirubinaemia. As we already have the term "hypobilirubinaemia," this latter usage should be dropped, and "hypochromia" should mean a reduction of the haemoglobin concentration of the corpuscle.—I am, etc.,

L. J. WITTS.

Guy's Hospital, Nov. 30th.

DEATHS ASSOCIATED WITH ANAESTHESIA

SIR,—Dr. F. L. Hoffman's letter in your last issue (p. 1009) comes very opportunely. He, in fact, issues a challenge of an international character, asking us to explain why, according to figures which he produces, anaesthesia appears to be three times as dangerous in this country as it is in America.

Britain is a very small, densely populated country, very stringently governed, with a system of death registration so strict that no single instance of a death associated with anaesthesia could possibly escape being recorded; in fact, many deaths so classified have little or no cause in anaesthesia itself. America is a very large country, divided up into a number of States, each with its own laws. Dr. Hoffman must prove to our satisfaction that their system of registration is as stringent throughout the States as it is in this country before any value can be given to his figures. But we are aware that the conditions in America are very superior to those prevailing here. Their splendid hospital system, conducted on business lines, through which rich and poor alike can pass on terms according to their means, finds no parallel in this country, where our best institutions are but the descendants of mediaeval monastic charities, often hampered by lack of funds.

In America anaesthesia is taken very seriously, while in this country it tends to become more and more the perquisite of the general practitioner. But while we admire the keenness of the American anaesthetists, and envy their better equipment, it is sometimes possible to detect in their writings an enthusiasm for results which cannot be supported by known physical laws or exact observation. We do not resent their criticism, but rather invite it, just as on occasions we are willing to offer it freely; and we keep a close look-out on their work with a view to improving our own methods, and theirs. The ignorance of the British public about this branch of surgery is well illustrated by the experience which befell me when called to administer an anaesthetic to a middle-aged lady, who preferred an attempt at induction with chloroform by an attending practitioner in the seventies, because, "You see, he brought me into the world." But Dr. Hoffman's letter comes as a resounding smack on the heads of those who have dominated the practice of anaesthetics in this country, and should cause them to sit up and take notice. These figures should be either disproved or explained.—I am, etc.,

W. HOWARD JONES.

London, W., Nov. 29th.

SIR,—The steady rise in the percentage of deaths from anaesthesia, which compares so unfavourably with the American figures, is very disturbing. To what extent is it due to the complicated apparatus so much in favour at the present day? At an operation I attended lately I particularly noticed how mechanical the whole process had become; how the eyes and hands of the anaesthetist were constantly occupied with his elaborate machinery, while the person most concerned—the patient—seemed left to the mercy of a system of tubes, valves, and bottles.—I am, etc.,

ERNEST H. GRIFFIN.

London, W., Nov. 28th.

ALLERGY AND THE "PROTEOSE"

SIR,—Dr. Freeman's remarks on the "proteose," isolated from the urine by Dr. Oriel in certain morbid conditions, reveal a misapprehension as to its significance, and incidentally to that of what he terms the dermal reaction. I will deal with the latter first.

To begin with, it is essential to distinguish between *epidermal* and *dermal* sensitization. The urticarial wheal is the commonest response when dermal hypersensitiveness exists. It is due, as the researches of Lewis and his colleagues have shown, to the liberation of histamine or some allied substance by the skin in response to injuries of various kinds. In a case of urticaria of internal origin, whether a known primary antigen—for example, fish or egg—is responsible (and this is relatively uncommon) or not, the liberation of histamine is presumably due to the damage resulting from the reaction of the antigenic substance with specific fixed antibodies in the dermal tissues. In a person who develops urticaria on the ingestion of a certain food the application of it to the skin by the scratch or intradermal method will naturally cause a local urticarial reaction.

When epidermal hypersensitiveness, on the other hand, is present, the reaction in the skin is an *eczematous* one, and it is now held that this depends upon sensitiveness of cells in the rete Malpighii. This type of cutaneous reaction is entirely distinct from the "triple response" that produces the urticarial wheal. It is apparently independent of histamine production, for even in eczematous persons I have never succeeded in provoking an eczematous reaction by bandaging histamine on the skin. To histamine the response is always urticarial.

Although an eruption consisting of mixed urticarial and eczematous elements may occur—for example, in some

sickness and fish poisoning, thus indicating simultaneous dermal and epidermal sensitization—it is exceptional, but an eczematous response to one antigen, and an urticarial reaction to another, in the same person, is not very uncommon. It is owing to this difference in cutaneous reaction according to the part of the skin in which the hypersensitiveness is localized, that dermatologists now use, in investigating cases of eczema, the contact or "patch" test, first indicated by Jadassohn, which consists in the application for twenty-four hours to the *uninjured* surface of the skin of suspected substances. As Sulzberger and Wise, MacKee, and others have recently pointed out, positive results—that is, an acute eczematous reaction at the site of application—are often obtained by this method after the scratch and intradermal tests have proved negative.

Two other points of great importance which have been established by the patch test are: (1) that phases of extreme hypersensitiveness, lesser hypersensitiveness, and non-sensitiveness occur, so that a person may give a strongly positive reaction at one time and a negative one at another, the non-sensitive phase is particularly likely to occur after an acute exacerbation of the patient's symptom; and (2) that one area of skin may be hypersensitive to a given irritant and another non-sensitive—for example, the skin of the eyelids may be sensitized and that of the forearm or other parts not so.

It will be clear from what has been said that to depend, as Dr. Freeman appears to do upon dermal reactions, provoked, I presume, by the scratch or intradermal tests, as evidence of hypersensitiveness or allergy towards a given substance is to misconstrue their significance. They indicate dermal sensitization, and no more. As has been seen, they may be negative even when another part of the skin, the epidermis, is sensitized. To expect them necessarily to be positive when other structures, such as the bronchial, intestinal, and uterine musculature or the mucous membranes of the respiratory and alimentary tracts, are sensitized is, to say the least of it, unreasonable.

To come now to the "proteose," the proofs that in certain acute and chronic allergic states it contains what may be justly termed a specific substance may be considered under two headings—experimental and clinical.

A. *Experimental*.—Dr. Freeman does not refer to the careful and laborious experiments carried out by Dr. Orvel upon the guinea-pig uterus according to the Dale technique. Some of them have been published[1] and I need only refer to two. If a guinea-pig be sensitized to milk, a typical contraction will be obtained by applying a solution of proteose prepared from a milk-sensitive person after he has taken milk, and also, of course, with milk itself. The proteose from a non-milk-sensitive person will give a negative result. Conversely, if a guinea-pig be sensitized by injections of the proteose from the milk-sensitive person, a uterine contraction will be obtained, not only with proteose, but also with milk. Dale's method of testing for specific tissue-sensitization is, of course, accepted as being the most reliable, providing the correct technique is employed, and these experiments, which have been repeated again and again, seem to me conclusive. With regard to cutis reactions, I can assure Dr. Freeman that positive dermal reactions from the scratch and intradermal tests can often be obtained with autogenous urinary proteose, the degree of reaction depending upon *the concentration of the solution*. Of much greater interest to me, however, is the fact that in certain cases of eczema of internal origin I have obtained a strongly positive *eczematous* reaction by applying a solution of the patient's own proteose to an area of undamaged skin for twenty-four hours (patch test), whereas proteoses from other patients gave negative reactions. In one patient the experiment was repeated three times upon different areas of skin with success. This seems to me sufficient proof that in these cases the patient's own proteose contained the substance to which the epidermis was sensitized.

B. *Clinical*.—For a long time past I have employed injections of autogenous urinary "proteose" with a view to desensitizing patients suffering from such conditions as chronic urticaria, angioneurotic oedema, eczema of internal origin, certain forms of prurigo, dermatitis herpetiformis, psoriasis arthropathica, and, more recently, uncomplicated psoriasis. In many of these patients other allergic symptoms, such as migraine, paroxysmal rhinitis, gastro-intestinal disturbance, and asthma, were present. As a result of very careful observations on a large number of cases, my conclusion is that it is not only specific, but incredibly and inconveniently so. My difficulty in many cases is to find a dose small enough to cause progressive improvement, and to avoid acute exacerbations of the patient's symptoms, or progressive deterioration in his condition. At first I worked with dilutions of 1 in 1,000,000 and 1 in 100,000, and gave increasing doses, often with very unpleasant results. I now employ minute doses—for example, 0·025 to 0·1 c.cm. of a dilution of 1 in 10,000,000, and, in some cases, for example, of the prurigo of Besnier with asthma (the most sensitive group of all), of a 1 in 100,000,000 dilution—and, having found the dose on which the patient improves progressively, I do not increase, but rather decrease the dose. The amount of proteose present in 0·05 c.cm. of the latter dilution must be infinitesimal, but I have patients who cannot tolerate more without reaction. This would seem incredible, but I can vouch for its truth, and that it is not the result of suggestion is shown by the fact that most of my hypersensitive patients have previously received injections of non-specific desensitizers, such as peptone, entero-vaccine, whole blood, aolan, etc., without any comparable reactions. An interesting point is that with proteose the usual time for a reaction to occur is on the third day after the injection, but this is not constant. Surely a substance which is capable of constantly producing acute exacerbations of a given patient's symptoms in a dose of, say, 0·1 c.cm. of a 1 in 1,000,000 dilution must be considered specific. The observations that Dr. Orvel and I have made on the clinical use of proteose have been amply and independently confirmed by others.

I cannot here discuss the actual nature and significance of the active substance which is contained in urinary proteose excreted in certain morbid states, but I see no reason to alter the opinion expressed in the original paper by Dr. Orvel and myself—namely, that it is a circulating antigen resulting from the action of one or more primary antigens on the person's own tissues (probably in most instances the hepatic cells). If this is so, it would correspond to the secondary antigen, denaturization product or anaphylotoxin of Vanwaring.—I am, etc.,

H. W. Berger

[illegible]

[1] *Proc. Roy. Soc. Med.*, July, 1931, xxiv, 55.

December 20th, 1924) that there is no evidence that an excess of the internal secretion of the pancreas is ever formed naturally. The only case he quotes with any resemblance to ours is, we think, the first case mentioned in the same article; but, from the published data, one would conclude that his case was chronic and not acute, and he attributes the cause to liver insufficiency and not to hyperinsulinism. We mentioned that we were able to collect from the literature twenty-four cases of acute spontaneous hypoglycaemia due to hyperinsulinism, but we were only indirectly concerned with the type of case in relation to which Dr. Cammidge's investigations and writings have given valuable information to the profession. If we have failed in our paper to give due acknowledgement to his work on the general problem of hypoglycaemia we offer him our apologies.—We are, etc.,

HENRY MOORE.

THE PITUITARY IN THE ETIOLOGY OF CANCER

SIR,—I have just read the interesting article by Dr. William Susman on the relationship between the pituitary and cancer, in the *British Medical Journal* of October 31st. May I call attention to the fact that I published, in 1930, in the *Klinische Wochenschrift* (November 8th and 15th), two articles dealing with the same subject—"Uben Beziehungen des Hypophysenvorderlappens zum uterus-carcinom." I have restricted my studies to the relationship of the anterior pituitary to cancer of the uterus for two reasons. First, I am a gynaecologist; secondly, my experimental work done on the subject reveals definite relations between the anterior pituitary and the stimulation of cervical epithelium, and also uterine epithelium. Articles by me on the latter subject have appeared in the *Proceedings* of the Society of Experimental Medicine and Biology (June, 1930); in *Surgery, Obstetrics and Gynecology* (February, 1931); also in the *Centralblatt für Gynaecol.* (September, 1930, and February, 1931). For many years I have been using radiation of the hypophysis, in conjunction with the local application of radium, in cases of cervical cancer. A report on this treatment is included in the last-mentioned paper. From these references it will be seen that I had already conceived of the relationship between the anterior pituitary and cancer, and also that we have put our ideas into practical effect during the past seven years.—I am, etc.,

I. HOFBAUER, F.A.C.S.

Professor [illegible] AND [illegible]

Baltimore, Nov. 18th.

MALIGNA[illegible]

SIR,—To an onlooker it [illegible] attempt appears to have been [illegible] *p*H in malignant cases [illegible] and production [illegible] (recent work on [illegible] this view), it would [illegible] the effect of neutralizing [illegible] must grow demand an [illegible] to bring the local *p*H to [illegible] What would be the effect [illegible] or a very weak solution [illegible] equilibrium is so easily disturbed [illegible] work with N/100 solutions, or even [illegible] dosage, and the specific effects of [illegible] would have to be studied, apart from [illegible] *p*H. A serious effect of excess of [illegible] deficiency of carbon dioxide, and as [illegible] depends directly upon adsorption of this [illegible] be local subnormal venous pressure and interference with circulation and nutrition. Infiltration in cases of accessible tumour should be a simple matter, and not fraught with danger.—I am, etc.,

RICHARD KERRY.

Montreal, Nov. 12th.

TEMPORARY TREATMENT WITHOUT CERTIFICATION

SIR,—Professor Robertson evidently takes a leisurely view of the therapeutic outlook in mental diseases. Are we asked to be grateful at the thought that forty years after the passing of the Lunacy Act (1890) the best that can be done for mental patients to-day is embodied in Section 5 of the new Act as at present being interpreted? And is it implied that this is the normal rate of progress, and that we are likely to have to wait another forty years for another "epoch-making" Act that will better the conditions of another 5 per cent. of the mentally sick? To suggest that in its limited version it still "marks an epoch from the legal point of view" would seem to indicate a reflection on the intelligence of our learned friends the lawyers, which surely cannot be intended.

Is it historically accurate to say that Section 5 of the new Act is a definitive expression of the intention of our legislators in regard to temporary patients? If so, after the work of the Royal Commission, the Board of Control, the Medico-Psychological Association, and various other committees and societies, verily it is a case of the mountain in labour bringing forth a mouse. But, with great respect, I venture to assert that the section dealing with temporary patients, as it is now being interpreted, does not express the original intention of the promoters of the Act. In support of this I quote from a leading article in the *Times* of January 2nd, 1931. Commenting on the coming into force of the Mental Treatment Act and the changes it was expected to introduce in the treatment of mental sickness, the writer says:

> "Certification has been relegated to its proper place as a measure to be taken only when all other measures have failed. In the future doctors will be as reluctant to adopt this measure, and so to confess their failure, as they are reluctant to-day to abandon the treatment of physical disease."

It was here obviously assumed that the application of Section 5 would have the effect of removing the [illegible]dering certification unnecessary in the great majority of cases, and this, in my opinion, was the view held by most of those connected in the working of the Act. I believe that it is erroneous to suggest that the public stand in no need of [illegible] naturally in the [illegible] that all the [illegible] assumed to exist in the justice [illegible] interpretation on the part of the Board of Control. Is there any valid reason why this cannot be adopted? The Board has exercised a wise discretion in the past in regard to certain sections of the principal Act; but if, as Dr. Percy Smith indicates, an amending Act will be required, I trust that, in view of the difficulties that have developed, no unnecessary delay will elapse before the matter is taken up in the proper quarter.—I am, etc.,

FREDERICK DILLON.

London, W.1, Nov. 23rd.

SIR,—The conjunction of the letters of Dr. Samuel and Dr. Whitwell on the above subject in the *Journal* of November 28th is most interesting. The latter gives [illegible] from a Dr. Unwin, who was a physician in [illegible]

House about a century before Dr. Samuel himself filled a similar post there, but the views of the former seem to be more modern. The medical certificate of insanity, designating a person bluntly a lunatic or an idiot, is a legal document prepared for the magistrate who intervenes, and is as permanent a legal record as is a conviction in the police court. In addition to the hardship of mental disorder, why should the patient have to bear this additional legal stigma of certification and the magistrate's order? Dr. Samuel states it is "a necessary preliminary to placing a person of unsound mind" under control. The law makes it necessary at present, but is this law necessary? Ought it not to be amended? Parliament decided about a year ago that in certain cases neither certificates nor legal intervention was necessary. The principle having been broken, could the practice not be extended?

Dr. Samuel states that "there was no real need for its conception"—namely, that of temporary treatment *without certification*. On the contrary, it has been a blessing to those to whom it applies. It applies, for example, to cases of acute delirious puerperal insanity, which often recover in from three to nine weeks. We have no such law for the poor in Scotland, and I shall not forget the rage of a working man, whose wife had to be removed from the Royal Infirmary to the Royal Hospital at Morningside, when he was told that his wife, a puerperal case, had to be certified a lunatic, and that a magistrate's warrant had to be obtained for her treatment. He could not understand the reason why. In England, at the present time, she would have been admitted under the Temporary Treatment Order, and, after recovery from her illness, could have held up her head without the stigma of unnecessary certification and commitment by a magistrate.

Dr. Samuel also states: "If it is infamous to become of unsound mind, surely the infamy is perpetrated by the disease itself." Disease, if not self-induced, is no infamy. It is not regarded by the patient as such, but a misfortune. It is a visitation from Providence, and must submit to it. It is a totally different thing when man intervenes and designates the unhappy sufferer by an opprobrious name, and places his medical treatment and commitment to an institution in the hands, not of a medical man, but of a magistrate, as if he were delinquent.

If the unsoundness of mind, and not certification, is the famous element, why did a clergyman remove his daughter, a voluntary patient, from an excellent mental hospital in England and bring her to Edinburgh a fortnight ago, when he was simply asked to get her certified? If a legalized medical certificate is necessary, why did Parliament take the extraordinary step—contrary to the advice of the Royal Commission—of abolishing both the certificate and the magistrate's order in certain cases? Why, if medical certificates and magisterial intervention are necessary, have we been able to treat without them, and under detention, if necessary, all recent and recoverable private patients in nursing homes for seventy-four years in Scotland, and that without a single legal action being brought during that time by those so treated?—I am, etc.,

GEORGE M. ROBERTSON.

University of Edinburgh, Nov. 28th.

SIR,—It is very satisfactory to learn on high authority that the Board of Control has correctly interpreted the phrase of the Mental Treatment Act, "incapable of expressing willingness or unwillingness to receive treatment," as defining the condition of one liable to be detained on medical authority in the absence of any judicial sanction. The Board's view coincides with that of a medical M.P., who explained in the columns of the *British Medical Journal* immediately after the passing of the Act that if an individual, on being asked, says that he is unwilling, that settles the question, and he cannot be detained under Clause 5.

In 1926 the British Medical Association presented to the Royal Commission on Lunacy a memorandum in which stress was laid upon the fact that it was the function of the judicial authority to order detention, that doctors were shielded by his intervention, and that it was not their desire to take upon themselves a role which is essentially judicial. During the last five years, however, as noted by Professor Robertson, the province of the mental specialist has so far advanced that the principle of the liberty of the subject has become subordinate to the opinion of the doctor as to what is the proper thing to do to the individual. Dr. Percy Smith looks back regretfully to the time before the enactment of legal safeguards, when a man could be committed on the request of a relative, fortified by the opinion of two doctors, without any of that "red-tape working" which is intended to secure that no one shall be unjustly deprived of liberty.

It remains to be discovered what the public, who hold in dread the very thought of imprisonment in an asylum, will have to say to devious methods of committal such as these; and whether they will not insist upon the repeal of the ill-designed Mental Treatment Act, which is so redolent of detention that every line of it is fraught with peril to the freedom which is our birthright.—I am, etc.,

London, E.12, Nov. 27th. S. E. WHITE, M.B., B.Sc.

SIR,—My limited experience is that the Board of Control is not rigid concerning the volitional status of temporary patients. Let us hope that uniformity of practice, when it comes, will tend in this direction.—I am, etc.,

GILBERT E. MOULD.

Kimberworth, nr. Rotherham, Nov. 24th.

PHYSICAL MEDICINE AND BIOPHYSICAL ASSISTANTS

SIR,—A few days ago I received a circular intimating that an association of registered biophysical assistants had been constituted for the following, among other purposes: "advancing the study and practice of physical medicine and making available to the public greater facilities for physical methods of treatment through the medium of registered workers." May I point out that the *Register of Bio-Physical Assistants* specifies that the competence of those whose names appear in it is limited to the application of direct current, ionization, faradic currents, sinusoidal currents, diathermy, high-frequency currents, light and heat, and ultra-violet light. These subjects embody but a small part of physical medicine, and I venture to submit that the wording of the passage quoted above gravely misrepresents the activities of biophysical assistants.

I am well aware of the fact that over 85 per cent. of the biophysical assistants are actually members of the Chartered Society of Massage and Medical Gymnastics, and I grant that the paragraph in question could apply to those members of the Chartered Society of Massage and Medical Gymnastics whose names appear on the biophysical assistants' register, but as it stands it is likely to be misinterpreted.

As regards "advancing the study of physical medicine," I can only proffer a pious hope that those people who rejoice in the unfortunate name of biophysical assistants will not identify themselves with biophysicists, and rashly carry their activities into realms of experimentation.

All those interested in physical medicine and its practice realize the regrettable state of affairs which results from the fact that no provision is made for tuition in physical methods or their prescription in the medical student's curriculum, with the result that, once qualified, he ignores the indications for physiotherapy, and is therefore unable to give certain cases the benefit of treatment by means of these methods; nor is he able to prescribe the treatment competently for some qualified and registered worker to carry it out.

No state of affairs could be more ludicrous than the existence of well-trained dispensers and the omission of the art of prescribing from the medical student's curriculum; and yet an analogous situation actually exists in regard to the branch of medicine under consideration. A large number of hospitals train students both for diplomas in medicine and diplomas in physical medicine (Chartered Society of Massage and Medical Gymnastics diploma), but they do not teach the former to employ the latter. The result is that the masseur or masseuse is made not only to carry out some specialized technique, but also to prescribe it, and only too often to diagnose the condition as well.

That a Physical Medicine Group should have been formed under the aegis of the British Medical Association is certainly a step in the right direction, and the near future may see the end of this vexatious position if this body directs its energies into the proper channels.—

I am, etc.,

P. BAUWENS.

London, W.1, Nov. 25th.

CHILD GUIDANCE CLINICS

SIR,—In the *Journal* of November 28th (p. 1010) appeared a letter under the above heading. It is not uncommon when reading a well-drafted advertisement of the latest synthetical preparation to conclude that it is just the thing to bring about the desired end; and conversely, when the desired end is named, for the purveyors of a synthetical preparation to say, "This will just touch the spot." Now Sir George Newman has recently outlined, with his usual illuminating insight, the fundamentals for the medical inspection of school children; and at once we are told that a preparation made up of "general and psychological medicine, educational, psychological, and teaching methods, sociology, and economics" as provided at a clinic is just it.

When will medical practitioners—men of science—come to realize that clinics at their best, apart from the home doctor, are poor things and only makeshifts, used to fill temporarily a vacuum; that a mass treatment system is contrary to all the dictates of medicine; that specialists left alone to carry out their respective fancies may be found to have harmed the child; and that the poor little mortal submitted undefended to "a psychiatrist, an educational psychologist, and a social worker," may be irredeemably ruined in its personality whilst yet in the bud?

What is there wrong with the general practitioner—the one scientist alone who goes in and out of the homes of the children; sees the environment of circumstances, the environment of characters there, breathing the atmosphere in which the child lives and develops? He is educated in innumerable medical schools for just this work, and yet constantly he is brushed aside directly something is found to be lacking in a desired complete medical service. If those who are really keen to help the child would get together to form public opinion and so influence legislation to provide an efficient domiciliary medical service for the child, then the home doctor selected by the family would take command and use, when and how he considers fit, these numerous specialists as his assistants, who, it would seem, at present are overwhelming the child with their synthetical preparations all controlled.—I am, etc.,

E. ROWLAND FOTHERGILL.

Hove, Nov. 28th.

ACIDOSIS AND KETOSIS IN CHILDREN

SIR,—There are some points in connexion with the pathology and treatment of acidosis and ketosis in children which are very confusing to the practitioner.

Insulin is being recommended for certain of these conditions. Thus Langdon Brown[1] says that in cyclical vomiting the only treatment of real value is water, dextrose, and insulin, and that insulin must be given for post-anaesthetic vomiting. R. J. Minnit[2] recommends its use in the parallel condition of post-anaesthetic vomiting of adults, without any mention of glucose.

Now it is well recognized that such ketosis has a different etiology from that of diabetes; in the latter the blood sugar is high, but not available to the tissues on account of the absence of insulin, while in the former the liver glycogen and blood sugar are both stated[3] to be low, indicating that the mechanism for dealing with sugar metabolism is in working order, but the sugar is deficient. In these cases the power of the patient to mobilize and produce insulin is not called in question, and this is a power which is much more effective and rapid in the healthy organism than that possessed by the artificially administered secretion.

In the case of post-anaesthetic vomiting several authors refer to the possibility of carbohydrate metabolism being interfered with by the intoxication, and Frew[4] states that glucose in these circumstances is useless, as it cannot be metabolized. I can, however, find no reference to a rise of blood sugar and the occurrence of glycosuria in such cases, and in their absence it is difficult to understand how insulin can help.

Will others give their experiences with insulin in such circumstances, and some biochemist explain why, if it is effective, this should be so?—I am, etc.,

ARNOLD H. SHENNAN, M.D., D.P.H.

Shabani, Southern Rhodesia, Oct. 25th.

RITTER'S DISEASE

SIR,—I saw a case of this rare disease the other day. I attended the mother, a primipara, at her confinement, which occurred on November 3rd. The accouchement was perfectly normal, without any assistance. She was a tinker's wife, robust and healthy, as was her mate, and the venue was a tent on "a blasted heath" on a dark and stormy night. The woman lay on a bed of rushes. The only dope the mother had was a modicum of whisky, administered surreptitiously while my back was turned—a time-honoured custom with these vagrants. The infant, a female, was plump, healthy-looking, and unblemished when born. Ten days later it presented a most astonishing appearance, pretty much like a half-skinned rabbit or moulting lobster. The skin had desquamated in large patches from the brow to the extremities, with the exception of small islands of skin here and there, which stood out in startling contrast to the prevailing red hue. The scalp alone was quite uninvaded. Unfortu-

ately the infant died of marasmus a week after the onset of this dermatitis exfoliativa neonatorum

The late Sir Malcolm Morris, in his *Diseases of the Skin* (fifth edition), states that he never saw a case answering to this description, nor ever heard of one reported in England. In this instance the exanthemata and congenital syphilis can be entirely put out of court. It would be interesting to know if any similar cases have been recorded in Great Britain. Ritter's mortality in these infants is 50 per cent.—I am, etc.,

D. MACKAY, M.A., M.B., Ch.B.

Central Medical Unit, 17th.

RHEUMATOID ARTHRITIS

SIR,—As Dr. Poynton states, recent correspondence on this subject has been most contradictory. Surely it shows the need for team work in the treatment of such a disease and for the trial of each and every so-called remedy. But, above all, let us apply the principles of orthopædic surgery, and thereby prevent those terrible deformities which are still seen in patients unable to walk or even feed themselves, and who, having failed in the past to get the treatment which the knowledge of these elementary principles should ensure, come to the orthopædic surgeon for the surgical alleviation of their distress.—I am, etc.,

B. WHITCHURCH HOWELL, F.R.C.S.

London, W.1, Nov. 30th.

SPINAL MANIPULATION

SIR,—In your issue of November 14th Dr. Edgar Cyriax takes exception to some of my statements with regard to spinal manipulation. Like Dr. Cyriax, I at one time believed that during joint manipulation I was breaking down adhesions and setting bones, but the fact that similar sounds can be produced in practically every normal joint has altered my conception as to what actually happens. This, however, opens up a large field, and another article dealing more fully with these matters is expected to be published at an early date.—I am, etc.,

THOMAS MARLIN.

London, W.1, Nov. 30th.

SUPPLIES OF CURARE

SIR,—For research purposes we wish to obtain supplies of the South American Indian arrow poison "curare." The quantities of this substance entering the markets are small at the present time. It may be that curare in gourds or small earthenware pots is held as a curiosity by some of your readers, who would be willing to let us have samples for trial.—We are, etc.,

H. HARTRIDGE.
RANYARD WEST.

Physiological Laboratory, St. Bartholomew's Medical College, Nov. 27th.

TESTIMONIAL TO DR. J. R. DREVER

SIR,—The compulsory retiral on account of ill health of the Scottish Medical Secretary, Dr. James R. Drever, is a great loss to the members of the British Medical Association in Scotland, while to him it means not only the loss of a business appointment, but a cessation of that service to his professional brethren which he has made his life work. As the first Scottish Medical Secretary, appointed on November 1st, 1919, he has had the responsibility of organizing the Association in Scotland and has done more than any other to co-ordinate its activities in a difficult territory. The Scottish Committee considers that not only would it be appropriate, but that many members would be glad to have the opportunity of expressing in a tangible way their appreciation of the work he has done for the Association, with their best wishes for his future. The Committee is accordingly issuing this appeal for contributions to a testimonial, which it suggests should, under the circumstances, take the form of a cheque. No figure is being specified, but as it is desired that the list of contributors should be as large as possible, it will be understood that sums of any amount will be gratefully acknowledged. Contributions should be sent to the Acting Scottish Medical Secretary, British Medical Association, 7, Drumsheugh Gardens, Edinburgh, not later than December 31st.—We are, etc.,

D. ELLIOT DICKSON, *Chairman*
JAS. B. MILLER, *Deputy Chairman*
GEO. A. ALLEN, *Past Chairman*
Scottish Committee

November 25th.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

The House of Commons this week carried a resolution authorizing the taxation of imports of non-essential fruit and vegetables. Subsequently the House debated the Government's Indian policy, as declared by the Prime Minister at the close of the Round Table Conference.

In the House of Lords, on December 1st, the Health Insurance (Prolongation of Insurance) Bill was read the first time. The Royal assent was also given to the Expiring Laws Act.

The Health and Housing Committee of Conservative and Liberal National members of Parliament has elected Dr. Fremantle chairman and Sir Cyril Cobb vice-chairman. The committee decided to set up subcommittees on housing and town planning, on national health insurance, on local government and Poor Law, and on public health. Sir E. Hilton Young, Minister of Health, arranged to address the committee.

The Government hopes to introduce a Children Bill during the present session.

Imported Fresh Milk

On November 30th Sir J. GILMOUR informed Major Braithwaite that his attention had been called to the importation of fresh milk from Denmark and Holland. Imported milk was not required to be accompanied by a certificate that it was produced under conditions comparable to those enforced in this country under the Milk and Dairies Order, but the Public Health (Imported Milk) Regulations made by the Ministry of Health in 1926 required the registration of all consignees of milk—other than condensed or dried milk—from abroad. Further, they laid down a standard of hygienic quality to which all such milk must conform. As regarded the danger of introducing the virus of foot and mouth disease he was informed that under the Danish law all liquid milk exported must have been pasteurized, and that although such pasteurization was not absolutely required by the Dutch law it was the practice in Holland to pasteurize milk intended for exportation to this country. He understood that imported fresh milk was again pasteurized in this country before it was distributed. The process of pasteurization was fatal to the virus of foot and mouth disease. No Marking Order applicable to imported milk had been made under the Merchandise Marks Act 1926, but the question of marking was to some extent covered by Section 1 of that Act.

Sweepstakes for Hospitals

Replying to Mr. White on November 30th, Sir HERBERT SAMUEL said no representation had been received by him previous to the present inquiry that the hospital authorities here desired a measure legalizing sweepstakes under proper safeguards as a means of assisting the hospitals of

this country. He understood that in June of this year the British Hospitals Association passed a resolution to the effect that "the association is not in favour of any amendment of the law affecting public sweepstakes which purports to be for the benefit of voluntary hospitals." Mr. WHYTE asked if the Home Secretary was aware that through the agency of legalized sweepstakes all the hospitals in the Irish Free State were in a better position to engage in research work and to give their patients efficient service, while in this country we were in a lamentable position. Viscount EDNAM asked whether any representations had been made to the Irish Free State that English hospitals should participate in the proceeds of the sweepstakes. Sir H. SAMUEL replied in the negative. Sir F. HALL asked whether, in the event of the Hospitals Association changing its attitude, the Home Secretary would consider the introduction of legislation to enable sweepstakes to be held here. No reply was given to this question.

Proprietary Medicines.—Mr. CHAMBERLAIN, replying to Sir Alfred Beit on November 21st, said he noted his suggestion for amending the Medicine Stamp Acts with the object of rendering all medicines protected by registered names or trade marks liable to duty, even if they be of a known, admitted, or proved nature, but the next Budget statement must not be anticipated.

Housing.—Sir E. HILTON YOUNG told Dr. Fremantle, on November 26th, that he would consider his suggestion of amalgamating the returns compiled with regard to houses occupied, erected, or reconditioned, and the houses and populations dealt with in clearance and improvement areas during the year and issuing the result in such a way as to provide a useful guide to progress made and needed. He told Mr. Salt that an estimate made by the larger urban authorities in England and Wales provided for the demolition of 57,000 houses under the slum clearance scheme of the Housing Act, 1930, during the five-year period commencing January, 1931. The number actually demolished up to September 30th last was 201. Replying to Mr. Thorne, Sir E HILTON YOUNG said 53,020 houses had been completed in England and Wales from January to October, 1931, under the Housing Acts of 1924 and 1930. He also told Mr. Robinson that he had no authority to make installation of apparatus for the refrigeration of food in blocks of working-class tenements a condition of the grant of any future subsidy. He doubted whether it would be either justifiable or practicable.

Conveyance from Hospitals.—Replying to Mr. McGovern on November 26th, Sir E. HILTON YOUNG said it was within the discretion of local authorities to arrange for the conveyance of persons to their homes on discharge from hospital, and many authorities already used this power. The problem of discharged children contracting chills, and also the danger of infecting other children in public conveyances, was one for the consideration of the local authorities. He did not think there was any need for his interference with their discretion.

Economy and Health Services.—Sir E. HILTON YOUNG told Mr Bevan, on November 26th, that he had no complete information as to the action which had been taken by local authorities generally after consideration of the circular on the review of local expenditure issued in September last, but information at his disposal did not suggest that local authorities had restricted the provision already made under their existing health services.

Approved Society Funds.—Sir E. HILTON YOUNG told Dr. Fremantle, on November 26th, that the total of the surplus funds of approved societies and branches, as ascertained at the third valuation, and the sum certified for distribution in additional benefits in the ensuing quinquennium, would be included in the report of the Government actuary on the Third Valuation of Approved Societies, which would be published very soon.

Notes in Brief

Mr. R. S. Hudson stated that the Government had not arrived at a decision in respect to the Hours of Labour Convention.

Medico-Legal

CHARGE OF ATTEMPTING TO PROCURE ABORTION

In Glasgow High Court, before Lord Morison and a jury, on November 25th, Rona Wotherspoon, a medical woman of Barrhead, was charged with having attempted to procure an abortion and with culpable homicide. After evidence had been heard, counsel for accused, Mr. J. D. Paton, K.C., tendered a plea of guilty on the charge of having attempted to procure abortion by the use of instruments on two occasions in the case of a woman now dead, and not guilty to that of culpable homicide. The latter charge was thereupon not proceeded with, and the jury formally returned a verdict in accordance with the plea.

In asking the judge to exercise mercy, Mr. Paton said that Dr. Wotherspoon held exceptionally high qualifications, and testimonials had been received from eminent men in her profession to her ability as a physician and surgeon, her devotion to duty, and her humanity. In all the posts she had occupied she had been exceedingly popular, alike with patients and colleagues. Her practice had diminished to a very small one, owing to ill-health, and he believed the offence was committed in a moment of madness due to stress and worry; there was no financial inducement in the case. The Crown had had her under observation, but although not absolutely normal, she was not certifiable.

The judge, in sentencing the accused to nine months' imprisonment, said that the case was one of the most pitiful in his experience. He had in mind the further punishment she might suffer at the hands of a professional tribunal. He thought he was entitled to take into account her high qualifications and reputation in making the sentence as lenient as possible.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

The following candidates have been approved at the examination indicated:

DIPLOMA IN MEDICAL RADIOLOGY AND ELECTROLOGY.—*(Part II)* W. Addey, W. Ahern, G. S. Bhargava, H. W. Davies, G. C. Fairchild, C. P. Goswami, J. J. O'Grady, T. Simpson.

UNIVERSITY OF LONDON

The following candidates have been approved at the examination indicated:

DIPLOMA IN PSYCHOLOGICAL MEDICINE *(with Special Knowledge of Psychiatry)*.—A. Guirdham, W. McC. Harrowes, Hilda M. Webb.

UNIVERSITY OF SHEFFIELD

Dr. Arthur J. Hall has been appointed Emeritus Professor of Medicine.

The Services

DEATHS IN THE SERVICES

Lieutenant Eric Charles George Darke, R.A.M.C., died in the British Military Hospital at Nasirabad, on November 8th, aged 26. He was the eldest son of G. J. Darke, Esq., of Upper Clapton, and was educated at Bart's, taking the M.R.C.S. and L.R.C.P.Lond. in 1927. He entered the R.A.M.C. as lieutenant on May 1st, 1929.

Surgeon Frederick William Collingwood, R.N. (ret.), died in a nursing home in London on November 23rd, aged 60. He was educated at the London Hospital, took the M.R.C.S. and L.R.C.P.Lond. in 1888, and after filling the post of resident medical officer at Charing Cross Hospital, entered the Navy as surgeon on February 22nd, 1888, but retired after a few years' service. As surgeon of H.M.S. *Persian* he accompanied Professor Sola's expedition to the South Seas in 1896. He had since been anaesthetist to the Samaritan Free Hospital for Women, and to the National Dental Hospital. He was a Member of Lincoln's Inn, and a Fellow of the Royal Society of Medicine, and was recently elected a councillor of the Royal Empire Society. During the war he was attached to the medical staff of the Lewisham Military Hospital.

Obituary

SIR DAVID BRUCE, K.C.B., D.Sc., LL.D.

M.B., F.R.C.P., F.R.S.

Major-General A.M.S. (ret.)

Sir David Bruce, who died on November 27th after a long illness, was born at Melbourne on May 29th, 1855, and from Stirling High School went to Edinburgh University, where he graduated as M.B. and C.M. in 1881. Entering the Army as surgeon on August 4th, 1883, he served in Malta and Egypt from 1884 to 1889, and from 1889 to 1894 held the post of assistant professor of pathology in the Army Medical School at Netley. In 1894 he was sent to South Africa, where he remained for seven years, becoming surgeon major in 1895, and went through the South African war. He was present at the actions of Elandslaagte and Laing's Nek, took part in the defence of Ladysmith, and served in operations in the Transvaal and Cape Colony, including the action at Belfast, was mentioned in dispatches in the *London Gazette* of February 8th, 1901, received the Queen's medal with two clasps, and was specially promoted to lieutenant-colonel on November 29th, 1900.

While stationed at Malta, in 1886, Bruce discovered the *Micrococcus melitensis*, the cause of Malta fever, or, as it is now called, Mediterranean fever; and was detailed by the Government of Malta to investigate an epidemic of cholera in 1887. In 1898 he was detailed by the Government of Natal to study horse sickness. In 1900–1 he served as a member of the commission to investigate conditions in South Africa with reference to the origin of dysentery in the field and its relation to enteric fever. Its report was presented to Parliament in 1902. From 1902 to 1911 he was a member of the Army Medical Service Advisory Board, but a great part of these years he spent on special duty as director of successive commissions appointed by the Royal Society for the investigation of various tropical diseases: Uganda, 1903, sleeping sickness; Malta, 1904–6, Mediterranean fever; Uganda again, 1908–10, sleeping sickness; Nyasaland, 1911–14, connexion, if any, between wild animals and diseases of man and of domesticated animals. During these years he became colonel, and was specially promoted surgeon general on April 1st, 1912, for his scientific services. He proved tsetse fly disease to be due to *Trypanosoma brucei*, carried from one animal to another by the fly *Glossina morsitans*, and sleeping sickness to be due to a trypanosome spread by the bite of the fly *Glossina palpalis*.

He was appointed commandant of the Royal Army Medical College on November 1st, 1914, and held this post throughout the war, till he retired on May 1st, 1919. During the war, in addition to his other duties, he served as chairman of the War Office Pathological Committee, and of the committees for the study of tetanus and of trench fever. In 1915 he delivered the Croonian Lectures at the Royal College of Physicians of London. On his retirement from the Army in 1919 he became chairman of the governing body of the Lister Institute.

Bruce served as president of the Physiological Section of the British Association in South Africa in 1905; as president of the Tropical Diseases Section at the International Congress of Medicine in 1913; as president of the Royal Society of Tropical Medicine and Hygiene from 1917 to 1919; and as president of the British Association in Canada in 1924, when he delivered to the meeting at Toronto, on August 6th, 1924, his presidential address on the prevention of disease. Many learned bodies in foreign countries conferred on him their honorary membership, and elected him a foreign correspondent — the Academy of Science of the Institut de France in 1918; the Academy of Medicine, Paris; the Biological Society of Paris, in 1919; the Société de Pathologie Exotique, Paris; and the Sicilian Academy of Science, Letters, and Art. At home he received many honours from the Crown and from academic bodies—F.R.S., 1899; C.B., 1905; D.Sc. Dublin, 1906; knighthood, 1908; LL.D.Glasgow, 1908; F.R.C.P.London, 1911; LL.D.Liverpool, 1918; K.C.B., 1918. In 1906–7 he served on the Council of the British Medical Association, and in 1908 the Stewart Prize was awarded him for his researches on Mediterranean fever.

Bruce was the author of over a hundred contributions to scientific literature, chiefly on Malta fever, tsetse fly disease, sleeping sickness, and trypanosomiasis, published mostly in the *Transactions* of the Royal Society. He also edited the *Journal of the Royal Army Medical Corps* from 1904 to 1908. In 1883 he married Mary Elizabeth Steele, R.R.C., O.B.E., who gave him invaluable assistance in his scientific work, and died only a few days before him.

The story of Bruce's connexion with trypanosomiasis is in effect the history of trypanosomiasis, and both man and his animals have been placed in his debt. In 1880 Evans, in India, showed that a trypanosome was the cause of "surra" in animals. At an even earlier date David Livingstone had described "tsetse fly" disease in Africa. But it was not until 1895 that Bruce was requested by the Governor of Natal to investigate the disease as it occurs in Zululand. He found that "nagana"—as it is called locally—was present in all the domestic

animals, and he was able to show that the tsetse fly —*Glossina morsitans*—did not inject a toxin, as was generally supposed, but was the carrier of a living organism from one animal to another. He sent an infected dog back to England, and this animal furnished the laboratories of Europe with specimens of what Plimmer and Bradford named *Trypanosoma brucei*. It was evident to Bruce that the fly procured the parasite from some definite source, and hunters and natives alike stated that wild game must be present where nagana is found. By means of inoculation experiments he found that the game could harbour the organism without themselves showing any symptoms. This preliminary work in veterinary protozoology opened the path to a more complete understanding of the trypanosomes of animals, and provided the means for the solution of the problem of sleeping sickness. This disease had been known from 1742, but until the beginning of this century it received little scientific attention. In 1902, however, Castellani, one of the first members of the then recently appointed commission of the Royal Society, discovered a trypanosome in the cerebro-spinal fluid of some patients suffering from sleeping sickness. Meanwhile Bruce had been asked to assist in the investigation, and on his arrival in Uganda in 1903 Castellani mentioned to him that he had found the organism in five out of fifteen cases of the disease. Bruce considered this to be of immense importance, and under his encouragement Castellani continued his work. It was ultimately found that the parasite was present in all cases.

Having ascertained with some certainty that the presence of the organism was the cause of sleeping sickness, Bruce proceeded to determine its mode of entrance into the human body. His previous knowledge of the similar tsetse fly disease of animals suggested that some insect might be involved, and he was soon able to show that the distribution of the malady, and of *Glossina palpalis*, a species of fly related to *G. morsitans*, were practically coincident. The evidence in favour of the fly theory was convincing, and by means of animal experiments he found that flies fed on infected patients were capable of infecting monkeys. In August, 1903, Bruce returned home, but the work of the commission still continued. In October, 1908, his work on Mediterranean fever completed, he returned to Uganda to continue his investigations locally. During this period he was able to confirm Klein's work, and show that, while the fly could mechanically transmit the trypanosome for a few hours after biting, it was able to remain infective for a much longer period, only, however, after an interval of time had elapsed. His investigations also showed that *G. palpalis* acts as the carrier of a number of animal trypanosomes of considerable importance, and he published several detailed papers dealing with these species. Bruce returned to England in the spring of 1910.

In April, 1911, the Colonial Office asked the Royal Society to inquire into the relation of the African fauna to the maintenance and spread of human trypanosomiasis, and, secondarily, into other trypanosome diseases of domestic animals. Sir David Bruce was appointed director of this commission, and he proceeded to Nyasaland in November, 1911. He remained there until March, 1914, with the exception of a break during the second half of 1913, when he returned home to give evidence before the Sleeping Sickness Commission. One of the chief conclusions arrived at by Bruce was that wild game constitute the main, if not the sole, reservoir from which the tsetse draws its infectivity. He also found that the human trypanosomiasis of Nyasaland was not caused by *T. gambiense*, the intermediate host of which is absent from that district, but by *T. rhodesiense*, which is carried by *G. morsitans*. He inclined to the opinion that this species was the same as that found by him in 1895 in nagana, and which bears his name. The Nyasaland work was not confined to human trypanosomiasis and measures for its prevention; many animal species were described in detail, and time was found to investigate the diseases caused by them. All of Bruce's conclusions are not accepted nowadays, though the majority are, but the impetus given by him and the commissions under his direction has been very far-reaching, and is still by no means expended.

By the death of David Bruce the world has lost a great scientist. A big man with big ideas, he possessed a special *flair* for getting at the truth, and supplied the driving power which, especially in tropical countries, is so necessary to bring work to a successful conclusion. Though brusque in manner and often hasty in speech, he would always listen to other people's suggestions and ideas, and would act on them if after consideration they seemed useful. He was fond of shooting, but was not much interested in athletic pursuits. In his later years he felt himself rather cut off from his old friends, and used to complain that he had lost most of them.

At the funeral service in London on December 1st the British Medical Association was represented by the Medical Secretary, Dr. Alfred Cox.

We are indebted to Colonel A. E. HAMERTON for the following appreciation of Sir David and Lady Bruce.

The death of both Sir David and Lady Bruce within the same week removes from the field of medical research the rare and happy partnership of a man and his wife who, for nearly forty-eight years, together formed a brilliantly successful unit devoted to pioneer work in the investigation of tropical diseases. By their combination of talent and mutual interest in the work to which they dedicated their careers, they alone initiated and perfected early in their married life—with meagre laboratory facilities, and when bacteriology was in its infancy—a series of masterly experimental investigations that culminated in two outstanding discoveries—namely, in 1887 the isolation of *Micrococcus melitensis* and the proof that it was the cause of undulant fever; and some eight years later the discovery of *Trypanosoma brucei* and the proof that it was the cause of "nagana," the fly disease of domestic animals in Zululand; also that the tsetse fly was the vector and the wild-game animals the definitive hosts of this lethal parasite. These great discoveries laid the foundation of a system of human and veterinary pathology and preventive medicine which they continued to illuminate until near the end of their lives, and which still occupies the minds of a host of investigators throughout the civilized world. Bruce's original reports on these discoveries are masterpieces of scientific reasoning based on experiment. They are as true to-day as when they were written, and—though the edifice of knowledge of which they are the base has grown immense—the original foundations were so well and truly laid that they have required no alteration. Happy is the man of science who can claim this to his credit!

Bruce was great, not because he was a supremely clever man in the common acceptance of the term—of whom it might be said, "He could have risen to the top of any learned profession to which he applied his mind"—but because he was original in thought, and he was no imitator. He had a constructive imagination. His mind, however, worked slowly; he pondered deeply and saw far into those workings of Nature that he investigated. Moreover, he had an indefinable intuition, almost mystical in its working, that enabled him not only to discern amidst a maze of possible courses the right path of investigation, and to plan his experiments accordingly, but to stick to it and avoid futile experimentation that

would lead only to a mare's nest. This faculty was of inestimable value in later life, when he became a director of teams of young workers on the various commissions for the further investigation of undulant fever, trypanosomiasis, and other diseases. He was quick to recognize any promising clue on data that emerged in the process of investigation, and to plan an orderly and conclusive line of experiments thereon. And he was just as quick to stop wasting time over experiments in which he "saw no light," to use his own expression.

But Bruce was not a good technician; he did not appear to have the manual dexterity or the patience to master the finicky details of laboratory technique. Here Lady Bruce was supreme; as a microscopist she had few equals. She had a master mind and hand for laboratory procedure, ingenious in devising apparatus out of all sorts of odds and ends, skilled as a bacteriologist and typist. She was also an artist of no mean merit, and a critic of literary output. She was, moreover, a truly noble woman. She excelled in the practice of all the virtues, which radiated from her nature with most effect in times of trial and difficulty in Central Africa. She was the happy possessor of a rare mental make-up, comprising unusual ability, tact, common sense in dealing with the ordinary affairs of life, and, above all, a real goodness of heart which inspired profound respect and admiration among all her colleagues on the Sleeping Sickness Commission. She had masculine courage and strength of character, with a suave femininity that had the best possible influence in promoting happy relations and harmony among all workers in the camp. She stands side by side with her husband among the immortals. The great work they did together in the service of humanity ranks with the highest, and remains an enduring monument in the Temple of Science.

[The photograph of Sir David Bruce is by Messrs. Elliott and Fry, London.]

ALEX WALTHEN NUTHALL, M.B., CH.M.BIRM. F.R.C.S.

Surgeon, Queen's Hospital, Birmingham; Consulting Surgeon, Children's Hospital, Birmingham

Alex Walthen Nuthall died suddenly at Queen's Hospital on November 20th, just as he was beginning his morning's work. He was born on July 24th, 1873, at Hazareebagh, in the province of Calcutta. His family had been connected with India for three generations, his great-grandfather having been an official in the British East India Company and both his grandfather and father having held high rank in the Indian Army.

He was educated at Westward Ho and the Birmingham Medical School, and qualified at the age of 22 years. His first appointment was at the Queen's Hospital as house-surgeon to the late Mr. Jordan Lloyd. After a year of residence, he went to St. Bartholomew's Hospital to study for the F.R.C.S., for which he qualified before he was old enough to receive the diploma. He then volunteered for active service as a civil surgeon in the South African war, and worked chiefly in Natal under Sir Frederick Treves. On his return to Birmingham he held the post of resident surgical officer at the General Hospital until, in 1902, he was appointed casualty surgeon at the Queen's Hospital. Four years later he became surgeon to out-patients, and in 1919 honorary surgeon. He was an active member of many of the hospital committees, and the high esteem in which he was held is reflected in the following resolution that was passed on the day of his funeral: "That this meeting of the Committee of Management of Queen's Hospital desires to place on record its sense of the great loss the hospital has sustained by the death of Mr. A. W. Nuthall, F.R.C.S., who for thirty years rendered most devoted service as a member of the honorary medical staff, first as a surgeon for out-patients and then as a surgeon on the full staff, which offices he filled with great distinction."

At the Children's Hospital Nuthall served as surgeon the maximum period of twenty-five years, and here, too, he was an active member of the committee of management. He had a great love for children, and it is no figure of speech to say his cheerful presence in the wards created and radiated an atmosphere of happiness. On his retirement on March 4th, 1929, a presentation was made to him by the Lord Mayor in recognition of the work he had done for the hospital. He was greatly interested in the movement to provide accommodation for middle-class patients who could not afford the expenses of an ordinary nursing home, and was one of the founders of St. Chad's Hospital, which was opened to meet this need just before the outbreak of war.

Nuthall was only prevented by colour-blindness from following the family tradition of entering the Army, but he always took the keenest interest in the Territorials. Before the war he held a commission in the 5th Royal Warwickshire Regiment, and a fellow officer writes that he was one of the best shots and one of the most popular officers in the battalion. Soon after mobilization he was transferred to the Royal Army Medical Corps, and proceeded to France with the 48th C.C.S., stationed for some time at Amiens. Later he was appointed officer in charge of the surgical division of the 52nd General Hospital in Salonica, with rank of major. Although this war service involved him in serious financial loss, it was characteristic of the man that no one ever heard a word of complaint from his lips.

He devoted much time to the activities of the British Medical Association, having been chairman of the Central Division of the Birmingham Branch, and, later, president of the Branch, as well as president of its clinical and pathological section. For the last ten years he had been representative on the Central Council. He was one of the honorary secretaries of the Annual Meeting of the Association at Birmingham in 1911, and in recent years had served on a number of committees at headquarters.

He was a keen Mason, and had twice occupied the Master's chair in Warwickshire lodges, once in the Grosvenor and, later, in the Lister Lodge, of which he was also a founder. He was awarded Provincial honours some three years ago, and was also a Royal Arch Mason.

Nuthall always took the greatest interest in cricket and football. He was an active supporter of the Warwickshire County Cricket Club, and in his earlier years a prominent player for the Moseley Rugby Football Club. He was a voracious reader, both of medicine and of fiction, and perhaps because he read so much he wrote but little. He was always greatly interested in pneumococcal infection, and in 1926 delivered the Ingleby Lectures at the University on pneumococcal peritonitis. He was fond of pointing out that pneumococcal empyemata were for the most part empyemata from the onset, and did not arise as complications of pneumonia; further, that in cases of pneumococcal empyemata and of pneumococcal peritonitis, no operative procedure should be undertaken during the acute stage, but that ten to fourteen days should be allowed to elapse after the initial rigor before attempting to drain either the thoracic or abdominal cavities.

We are indebted to colleagues at the Queen's Hospital for the following appreciations.

L. G. J. M. writes: His handsome, kindly face and lovable nature—I never heard that he ever made an enemy in his life, never heard an ill word from him or of him. He was loved by his colleagues, the students, and his patients. I saw him in severe illness, in great pain—patient and courageous. I saw his fortitude and resignation during many years of the fatal illness of his wife, to whom he was devoted. He was a true sportsman through and through, and incapable of doing anything mean or underhand. In committee he was always ready to help with sound judgement, but always insisted on trying to make out some sort of case for a lost cause or a rejected candidate. He had no ambition to be either a great surgeon or a wealthy one, and shunned self-advertisement in every form.

W. B. writes: The outstanding features of Nuthall's character were modesty, absolute rectitude, and ever-ready helpfulness. He was friendly and cheerful to all who came in contact with him, but was very reserved. He never pushed himself or his work prominently forward, and was very tolerant of the opinions of others. Knowing him intimately for more than thirty years, I know that nothing selfish or unkind ever influenced his actions or opinions. He never allowed his own interests or advancement to stand in the way of doing and saying what he thought to be right, and his standard of professional rectitude was a very high one. His readiness to help his colleagues and his patients, at no matter what personal inconvenience, was unvarying. He was a true and loyal friend, and his passing leaves a deep sense of personal loss in the hearts of many. As a surgeon, Nuthall was widely read, skilful, and most conscientious, always putting the interests of the patient in the forefront. He devoted himself whole-heartedly to his hospital work, and gave more time to it than he could really spare. He was a man who quietly, unostentatiously, and consistently gave of his best to rich and poor alike. He was a popular teacher, a first-class all-round general surgeon, and a most loyal and helpful colleague.

FRANK HAWTHORN, D.S.O., M.D.

Consulting Surgeon to the Fleming Memorial Hospital for Sick Children, Newcastle-upon-Tyne

As noted in our last issue, Colonel Frank Hawthorn died on November 20th after a brief illness.

A Newcastle man, he was the son of Dr. John Hawthorn, who was an eminent general practitioner as well as public vaccinator in the city. Hawthorn was educated at the University of Durham College of Medicine, and eventually followed his father as lecturer on vaccination in the College. He carried on a general practice in the centre of the city, but the great interest in his life was his work as surgeon to the Fleming Memorial Hospital for Children, where he worked for thirty years, only retiring on attaining the age limit last year.

He gave voluntary service to many of the auxiliary benevolent institutions in the city, and, in particular, took a keen interest in the Dame Margaret Home for Children at Washington—Dr. Barnardo's Northern Branch—where he worked for twenty-five years, and of which he was joint secretary. He was also a member of the committee of the W. J. Sanderson Home for Crippled Children. He supervised the medical services of the Church Lads' Brigade and the Church Girls' Brigade of the North-Eastern district. He was a member of the Newcastle-upon-Tyne Division of the British Medical Association, and was joint honorary secretary of the Section of Orthopaedics and Diseases of Children at the Annual Meeting of the Association at Newcastle in 1921.

In the midst of his work he found time to take a prominent part in the R.A.M.C.(T.F.). Beginning as surgeon lieutenant to the Newcastle-upon-Tyne R.G.A. in 1906, he became connected with the 1st Northumbrian Field Ambulance (T.F.) in 1908, and in 1913 was lieutenant-colonel in command. He saw active service in France from 1915 to 1917, was three times mentioned in dispatches, and was awarded the D.S.O. He was made brevet colonel in 1923, and retired in 1926.

Throughout a busy and useful life Frank Hawthorn earned, wherever his activities led him, the respect and esteem of professional colleagues and citizens alike. He was honoured by his medical brethren in every position of trust in local affairs, and will always be remembered for his conjunction of a modest and lovable disposition with the highest ideals of firm purpose, and devoted service in the interests of the community in which he lived.

[The photograph reproduced is by James Bacon and Sons, Newcastle-upon-Tyne.]

The death took place at St. Andrews, Fifeshire, on November 27th, of Dr. HENRY WILLIAM LAING. He was born in 1854 at Bridge of Earn, Perthshire, where his father practised medicine. After his medical course at Edinburgh he took the licentiateship of the Royal College of Surgeons there in 1875, and in the same year graduated M.B., C.M. at Edinburgh University. After proceeding M.D. in 1879 he was for a short time assistant to his father, and later went to Kirkcaldy, where he built up a large practice and acted as medical adviser to the Kirkcaldy Hospital. He practised for twenty-seven years in Kirkcaldy, and in 1914 retired and took up residence in St. Andrews. He had been associated with the Territorial Force, and on the outbreak of war served as medical officer to the 7th Battalion of the Black Watch at home, becoming ultimately brevet lieutenant-colonel. After the war Dr. Laing again settled in St. Andrews, and from 1919 acted as honorary medical superintendent of St. Andrews Cottage Hospital. He is survived by a widow and by a son and daughter.

Medical News

The autumn dinner of the Irish Medical Schools' and Graduates' Association was held at the Piccadilly Hotel, London, on November 26th; Mr. Andrew Fullerton, ex-President of the Royal College of Surgeons of Ireland, was in the chair. The principal guests were Sir Thomas Maloney, Lord Chief Justice of Ireland, and Dr. W. G. Willoughby, President of the British Medical Association. Following on the toasts of "The King" and "The Prince of Wales and other members of the Royal Family," Mr. W. J. Corbett, F.R.C.S., proposed the toast of "The Guests," referring to the regretted absence of Mr. J. W. Dulanty, the High Commissioner for the Irish Free State; he welcomed in his place Sir Thomas Maloney. The two chief features of the B.M.A., Mr. Corbett said, were the protection of the general practitioner and the promotion of scientific work. In responding for the guests, Sir Thomas Maloney illustrated the progress of surgery and of public health in Ireland by several amusing anecdotes. Dr. W. G. Willoughby, toasting "The President and Association," paid a gracious tribute to Sir Thomas Maloney. Dr. Willoughby claimed association with Ireland, and said that five or six generations back there

had been an infusion of Irish blood in his own family. The witty speech which followed bore out the truth of this assertion. Referring to the relation between the medical officer of health and the general practitioner, Dr. Willoughby said that he himself was a physician first and a medical officer of health second. Mr. Andrew Fullerton reminded his audience that many of them there were earning their living in a strange country, but he deprecated an excess of patriotism, the evil effects of which were so obvious to-day, and urged that the spirit of international co-operation should prevail.

The winter dinner of the Australian and New Zealand Medical Association in England will be held at the Trocadero Restaurant, Piccadilly, on Friday, December 11th, at 7.45 for 8 p.m., with Mr. T. P. Dunhill in the chair. Sir John Thomson-Walker and Professor William Wright will be the official guests. All medical visitors from Australia and New Zealand, whether already members of the association or not, are cordially invited to be present. The honorary secretaries are Mr. E. T. C. Milligan and Mr. Philip Jory, 26, Queen Anne Street, W.1.

The thirteenth annual reunion dinner of the officers of the 29th General Hospital will be held at the Trocadero Restaurant, London, W., on Saturday, December 12th, *Lieut.-Colonel S. H. Withers presiding. Members desirous* of attending should apply to the honorary secretary, Captain A. Percy Groves, Heronfield, Meadowcourt Road, Leicester.

A meeting of the Court of Governors of the Middlesex Hospital will be held in the large lecture theatre of the Medical School on Wednesday, December 9th, at 11 o'clock. H.R.H. Prince Arthur of Connaught, chairman of the hospital, will give an account of the progress of the reconstruction scheme, and in particular of the work just beginning on the final section of the new east wing and cross-piece.

At a meeting of the Pharmaceutical Society of Great Britain, to be held at 17, Bloomsbury Square, W.C., on Tuesday, December 8th, an address will be given by Mr. M. D. Perrins of the Home Office, upon "The international illicit traffic in drugs." The president will take the chair at 8.30 p.m.

A meeting of the National Baby Week Council was held at 117, Piccadilly, on November 27th, when the chairman, Sir Gomer Berry, gave an address, and the report of the executive committee was presented by its chairman, Dr. Eric Pritchard. A discussion on "Where wise spending is good saving" was opened by Dr. W. G. Booth and Dr. A. S. Hebblethwaite, and an announcement about the campaign for 1932 was made by the joint honorary secretaries, Dr. D. H. Geffen and Dr. Sophia Friel.

At a meeting of the Paddington Medical Society on Tuesday, December 8th, at the Great Western Royal Hotel, at 9 p.m., Mr. W. McAdam Eccles will give an address, entitled "Pitfalls in the anatomy, diagnosis, and treatment of hernia."

The Fellowship of Medicine and Post-Graduate Medical Association announces that the last lecture of the "Prognosis" series (on goitre, with special reference to thyrotoxicosis) will be given by Mr. Cecil Joll at 4 p.m., on December 9th, at 11, Chandos Street. Free clinical demonstrations will be as follows: Monday, December 7th, at 6 p.m., in the St. John's Hospital, Leicester Square, Dr. S. E. Dore. Tuesday, December 8th, at 3.30 p.m., clinical lecture room, Royal Northern Hospital, Mr. Hamilton Bailey. An evening course of lectures on endocrinology will be given by Dr. W. Langdon Brown, at 11, Chandos Street, on Mondays and Fridays (January 11th to 29th) at 8.30 p.m. (fee 2 guineas, or 10s. per lecture). The 1932 list of special courses is now ready. An evening course (lectures and demonstrations) for the April M.R.C.P. examination will be held in February and March, 1932; numbers will be strictly limited to twenty-five. The syllabus will be ready shortly.

A week-end course on common disorders of childhood and their treatment will be given at the Hospital for Sick Children, Great Ormond Street, W.C., on Saturday December 12th, from 9 a.m. till 4 p.m., and on Sunday, December 13th, from 10 a.m. till 12 noon. The course, which is suitable for those in general practice, will be free to medical practitioners; those intending to be present should notify the dean of the Medical School at the Hospital.

The programme of the South-West London Medical Society includes the following papers: December 9th, scarlet fever, Dr. J. D. Rolleston; January 13th, diseases of the hip-joint, Mr. Gordon Pugh; February 10th, complications in pregnancy and labour, Dame Louise McIlroy; March 9th, pruritus, Dr. W. J. O'Donovan; April 13th, common disease of the mouth, Mr. Cecil Rowntree. On May 25th Sir Humphry Rolleston will deliver the Bolingbroke Lecture, entitled, "Advances in medicine during the last fifty years." All meetings are held at the Bolingbroke Hospital, Wandsworth Common, at 8.45 p.m.

A Geneva University Club has been founded to afford students and teachers from Geneva University who are resident in England opportunities for meeting socially at least twice a year. Subscription, 5s. Dinner, Wednesday, December 16th, at 7.45 p.m.; tickets 10s. 6d. Particulars from the secretary, 31, Highbury Place, N.5.

At a meeting of the Optical Society, to be held in the Imperial College of Science and Technology, South Kensington, on *Thursday, December 10th*, at *7.30* p.m., a paper on a new photo-electric spectrophotometer will be presented by Drs. F. Campbell Smith and Ensor R. Holiday of the London Hospital. A device for focusing projectors will be demonstrated by the research staff of the General Electric Company, Ltd., and W. Watson and Sons, Ltd., will show microscopes and a modification of the usual eyepiece camera.

H.R.H. the Duke of Connaught, Grand Prior of the Venerable Order of the Hospital of St. John of Jerusalem, has appointed Colonel C. I. Ellis, M.D., of Torquay, surgeon-in-chief of the St. John Ambulance Brigade as from November 23rd, 1931. The personnel of the St. John Ambulance Brigade in England, Wales, and Ireland is 55,121 men and women, and 7,356 cadets (boys and girls), a total number of 62,477. Besides this number there is the brigade over-seas; in fact, every British Colony or Dominion either has a division of the brigade or a teaching centre of the St. John Ambulance Association.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are *MUSEUM* 9861, 9862, 9863, and 9864 (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediocra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Britmedia, Dublin*: telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS

Inhalation Therapy

Dr. C. H. AUTY (Harlesden) wishes to get in touch with other medical men who practise inhalation therapy, with the object of forming a society to advance this section of medicine.

"Cold Back"

"P. M." writes: Could any reader tell me anything of the etiology and treatment of "cold back"? This is, I believe, a fairly common complaint among women, and, although not incapacitating, certainly annoying. My patient is aged 28, stout and otherwise healthy, but complains bitterly of this coldness. Warm clothing does not, so she says, help in any way. The region affected is the lumbar area.

Nausea and Vomiting of Pregnancy

Dr. DOUGLAS ANDREW (Arlesey, Bedfordshire) writes: In reply to Dr. Lawson Steele's query concerning sickness and nausea during pregnancy, the cause of this condition is still not definitely known. The chief among several theories advanced in this connexion are: (1) increased irritability of the nervous system; (2) deficiency of the hormone secreted by the corpus luteum; (3) a mild degree of toxaemia. These points must be remembered when treatment is undertaken. I have found that great benefit usually results from the following regime. (1) During the first three months of pregnancy the patient is advised to adhere to a fruit diet as strictly as possible. In my opinion meat of all kinds and fatty foods should be absolutely avoided. (2) Regular exercise is necessary. (3) Bowels must be kept absolutely regular. I have found phenolphthalein in doses of 1 to 2 grains the most useful drug for this purpose during pregnancy. I usually prescribe a saline draught containing 5 to 10 grains of potassium bromide at night. If sickness still persists 3 minims of tincture of iodine in a tumblerful of water can be tried. The chloretone 5-grain capsules (Parke, Davis and Co.) are very useful in most cases.

Naevus

"V. S. M." writes: In reply to the letter of "Inquirer" about the treatment of a naevus, whilst I am in no way an expert in their treatment, I would like to answer his questions. (1) The prognosis is good if he is satisfied with a flat, white scar. (2) Radium appears to give the best result, though alcohol injections may be used. If, however, the injections are not successful the radium treatment is made more difficult. (3) The earlier the treatment the less will be the scar, as these naevi rapidly increase in size.

Income Tax

Temporary Residence in the United Kingdom

"I.M.S." joined the Indian Medical Service on August 4th, 1931, from which date he has been receiving salary and allowances. He arrived in England from Australia just before taking up the appointment, and will be leaving this country for India about February 12th, 1932. Will he be liable for income tax?

*** If the salary, etc., are paid from British funds he is liable, however short his stay in the United Kingdom. If the source is Indian he would seem to be exempt, unless he spends six months in this country during the year ending April 5th, 1932. In calculating the period of six months temporary periods spent outside the United Kingdom can be ignored.

LETTERS, NOTES, ETC.

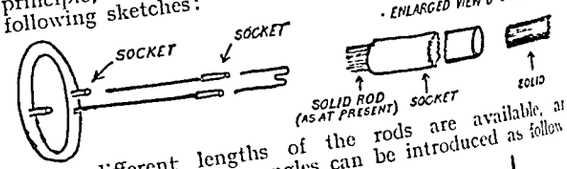
Survival after Prostatectomy

Mr. ANDREW FULLERTON (Professor of Surgery, Queen's University, Belfast) writes: I have just received an unsolicited letter from a clergyman upon whom I operated for enlarged prostate in October, 1911—that is to say, over twenty years ago. The patient states that he was born on November 21st, 1842, so that he is now in his ninetieth year. From my experience of these cases I am convinced that a patient who survives the operation is often rejuvenated, and may enjoy much better health than he has for years before.

Climatic Health Resorts of India

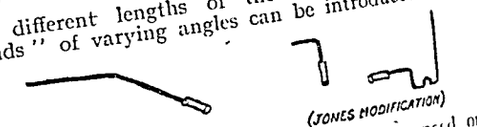
Dr. A. P. CAWADIAS (52, Wimpole Street, London, W.1) writes: May I make an appeal through the *Journal* to colleagues practising in India for some recent documents referring to the therapeutical action of the climatic health resorts of India. Professor Piery of Lyons has undertaken the publication of a big treatise of "medical climatology" with the object of collecting the more recent documents of the therapeutical effects of climatic health resorts all over the world. He has done me the honour to ask my collaboration, and in the part that has fallen to my lot are included the Indian climatic health resorts. As I have found very scanty information on this point in the literature, I should be much obliged for any more direct information from physicians who know these resorts personally.

A Surgical Link with the Past



Mr. N. DUGGAN (Worcester) writes: To-day I was able to congratulate a patient on attaining her eightieth birthday. Fifty-five years ago, when she was 25, she was operated on by Sir Spencer Wells in a London nursing home for an ovarian cyst. This would appear to be one of the oldest living cases of laparotomy. She takes pleasure in describing how the great surgeon visited her during her convalescence, presenting her each day with a nosegay concealed in his top-hat. When the time came for her to leave the home she was so affected at parting from her benefactor that she cried a little, and was rewarded by an affectionate kiss. *Tempora mutantur!*

Domestic Refrigerators



VISCOUNT BURNHAM writes: Whilst we have made remarkable progress in connexion with national and domestic hygiene, it is still surprising that we do not insist upon provision being made in every new house that is built for the installation of a refrigerator. Nothing can be more important than the purity of our food, and yet in hundreds of thousands of homes food has more or less to take its chance with the bacteria which are always attacking it. The number of cases of illness traceable to impure food must be very considerable. Most, if not all of them, might be avoided by wise spending. Will not the Ministry of Health look into this matter?

The Thomas Splint

"WATERFOOT" writes: It has appeared to me that one great drawback to the Thomas splint is the large number of these which have to be kept in stock to ensure possessing one of proper size. I offer the suggestion, for what it is worth, that the iron parts should be made on the pin and socket principle, and thus be interchangeable, as shown in the following sketches:

Thus different lengths of the rods are available, as "bends" of varying angles can be introduced as follow

And so on. The leather-covered ring parts need only be in, say, three sizes for the leg, and perhaps two for the arm

Phimosis and Circumcision

Dr. J. M. MORRIS (M.O.H., Neath) writes: Beginning infant welfare work in 1915, one of the first things I noted was the large number of boys, at least 75 per cent., with adherent prepuce. For some time I freed a good many, a proceeding alleged by writers to be painless, a feature outside my experience. Eventually I got somewhat fed up with this, and thought that it would be well to see what had become of the tight prepuces of those unfortunates born before infant welfare began. I made a survey of all boys in my school area, some 1,900, and these were the facts. Excluding about thirty, who had had circumcision, for reasons unknown to me, but, judging by age groups, seemingly carried out in waves of enthusiasm, I found one very definite narrow preputial opening, for which circumcision or stretching would have been beneficial, and one doubtfully requiring treatment. In all other cases the foreskin was in a most lax condition; to retract was almost like pulling up one's trouser leg. This was found at the age of 5 just as much as at 14.

Sex Equality

A correspondent, who had hitherto shared our belief that the prostate is an organ peculiar to the male sex, sends us an extract from the advertisement columns of the *New York World* of November 22nd. The advertisement is headed boldly: "PROSTATITIS. 30% of Men and Women above Fifty Suffer Needlessly. They Live in Dread of by Day and Their Rest is Disturbed at Night." Is prostatectomy to be included among gynaecological operations?

Vacancies

Notifications of offices vacant in universities, medical colleges and of vacant resident and other appointments at hospitals will be found at pages 78, 79, 80, 81, 82, 83, 86, and 87 of our advertisement columns, and advertisements of partnerships, assistantships, and locumtenencies at pp. 84 and 85.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 311.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

511 Cardiac Symptoms Simulating Abdominal Conditions

G. R. BURNS (*Canadian Med. Assoc. Journ.*, October, 1931, p. 424) records three cases with a view to calling attention to the fact that at times common cardiac conditions may very closely simulate acute conditions in the abdomen; this may lead to unnecessary operations, and even the death of the patient. The more or less pronounced features in particular cases were pyrexia, leucocytosis, abdominal pain, muscular spasm, shock, and such minor indications as vomiting, diarrhoea, nausea, or eructations. To guard against the erroneous interpretation of such manifestations a very careful history of the case must be secured, and a scrupulous and exhaustive examination of the cardio-vascular system is essential. In fifteen months Burns saw four cases of coronary thrombosis which had been sent into hospital diagnosed as acute abdominal emergency. Of this condition the most puzzling cases are those in which death is delayed, and the anginal pain is not relieved by amyl nitrite, but only by morphine in large doses. The author discusses the way in which the puzzling abdominal symptoms are evoked, and mentions particularly the blood pressure (a fall from a previously high figure) due to infarction, the fever, and the leucocytosis. The fear of impending death may cause the patient to lie quietly in bed, instead of struggling violently as in gall-bladder colic. The electrocardiograph is the final court of appeal, but the character of the heart sounds and the evidence of cardiac failure may suffice to indicate the correct diagnosis. Similarly in angina pectoris there is the fear of impending death, and the onset (after exercise, an emotional outburst, or a heavy meal) demands consideration. The history in such a case will usually bring out evidence of limitation of the cardiac reserve. Paroxysmal tachycardia, with epigastric pain, but not excessive increase of the heart beat, is difficult to recognize at first. Acute fibrinous pericarditis, on the other hand, is usually not a primary condition, and some adjacent focus of disease may be found, usually a tuberculous lesion in the lungs or mediastinum.

512 Vincent's Disease

R. I. RIZER (*Minnesota Med.*, October, 1931, p. 901) urges the need of more co-operation between the physician and the dentist in detecting and treating Vincent's disease, which, he thinks, is becoming more prevalent, possibly owing to the failure to recognize carriers. In 160 persons Miller found Vincent's spirochaete in 77 per cent. Brams discovered its presence in the crypts of 82 per cent. of 100 pairs of tonsils. It has not been found in the mouths of edentulous people, and rarely in normal mouths. The organism is probably saprophytic until some conditions arise, such as erupting third molar teeth, pyorrhoea, unclean mouths, tobacco and mercurial stomatitis. It is often associated with adenoids, diphtheria, measles, syphilis, scarlet fever, purpura, sepsis, diabetes, tuberculosis, malnutrition, scurvy, and malignant growths; in such cases it may multiply and become the dominant symptom of the pathological condition. In patients with red and swollen gums about certain teeth the routine examination of a dried smear, fixed by heat and stained by gentian violet, shows a very high percentage of Vincent's spirochaete as the cause of the condition. The physician should order a liberal general diet; condiments, pickles, and highly seasoned food should be avoided. Smoking, and the use of toothpicks and dental floss are prohibited. Strict instructions about the methods of infection should be given. The dentist should employ a regime of mild instrumentation only, avoiding any trauma that might lower the resistance of the soft tissues. A mouth wash of equal parts of alcohol, hydrogen peroxide, and glycerin is useful; a soapy toothpaste aids in removing the organism. Corrective dentistry should not be begun until the soft parts have a healthy appearance. When the infection is recognized early, and proper treatment is instituted, the prognosis is excellent, provided that the physician and dentist co-operate.

513 Whooping-cough as an Alleged Precursor of Tuberculosis

A. SUNDAL (*Tidsskrift f. d. Norske Laegefor.*, October 15th, 1931, p. 844) records observations from the Ullevaal Hospital in Oslo which give little support to the belief that whooping-cough is often responsible for the development of tuberculosis. Among a series of 24 patients, all of whom were examined radiographically on admission, six were found to be Pirquet-positive once or more often in the course of the illness. In every case in which there was a possibility of tuberculosis, a new skiagram was taken weekly. The negative Pirquet reactors were also repeatedly re-examined with the Pirquet test. In three cases, a positive Pirquet reaction became negative during the illness, again becoming positive between the second and fourth weeks. In all the Pirquet-positive patients the *x*-ray examination showed signs of involvement of the lungs, but only in one case were *x*-ray changes observed which could be interpreted as indicating activation of the pulmonary focus in the course of the whooping-cough. There was, however, a child, born in 1924, who had been treated in a sanatorium for tuberculosis of the bronchial glands some years earlier, and whose tuberculosis was activated by the whooping-cough.

Surgery

514 Osteomyelitis of the Os Calcis

F. J. GAENSLEN (*Journ. of Bone and Joint Surg.*, October, 1931, p. 759) emphasizes the difficulty of successful surgical approach to lesions of the os calcis, especially in cases of extensive destruction of the interior of the bone due to osteomyelitis, and when the adjacent joints or tarsal bones are involved. Medial or lateral approaches give inadequate exposure, and recurrence or persisting sinuses result from the incomplete removal of diseased bone. Eleven cases are reported of osteomyelitis of the os calcis, nine pyogenic and two tuberculous, which were operated upon by the split-heel method. In most of the cases there was a central lesion involving a varying amount of cancellous bone, while the cortical bone was uninvolved or perforated by the sinuses. In some cases the disease had invaded the astragalo-calcaneal joint as well as the mid-tarsal joint. In no case was there any involucrum formation surrounding the os calcis, nor was there extensive periosteal separation with large areas of dead cortical bone. The first case operated on by the split-heel method was a girl, aged 11; a sand burr had penetrated her foot, which was red, swollen, and painful with a discharging sinus over the ankle. Clinical and *x*-ray examinations indicated an extensive and progressive involvement of the os calcis and adjacent tarsal bones. An operation was performed, the mid-plantar incision being chosen, and the Achilles tendon being split in the mid line of the lower three or four centimetres. Sequestra were removed, and granulation tissue was taken from the interior of the os calcis and the lower portion of the astragalus; the wound was packed with glycerin gauze, and the limb was immobilized on an anterior moulded plaster. Final healing ensued about four months after the operation, and the end-results were a slight limp, a painless scar, and limitation of the sub-astragalar

mobility. In most of the other ten cases the results were very satisfactory, and the split-heel method of approach is strongly advocated for the following reasons: periosteal stripping and removal of healthy cortical bone is avoided, good exposure is given; and complete excision is avoided in most cases. No plastic operation has been necessary in any instance, and in only one case of chronic tuberculous abscess has there been recurrence which required further surgical treatment.

515 Traumatic Aneurysm of the Temporal Artery

K. H. ERB and E. HAHN (*Zentralbl. f. Chir.*, October 17th, 1931, p. 2610), who record three personal cases, illustrate the rarity of traumatic aneurysm of the temporal artery by the following statistics. Among 332 aneurysms collected by Sprunner-Merz in 1877, it was found in only 2.5 per cent.; in 982 cases collected by Simon in 1917, including all hitherto published war aneurysms, the percentage was only 0.8, and in 195 war aneurysms collected by O. Hahn in 1921 it was barely 1. In view of the rarity of the occurrence, it was a remarkable fact that the three cases of the present authors occurred in the course of a single term at the Königsberg University Surgical Clinic. The patients were students aged from 21 to 23; the lesion was caused by duelling, and was a typical false aneurysm. The symptoms were slight, the principal trouble being a sensation of throbbing in the aneurysmal sac. The authors add that spontaneous cure is possible, but the simplest operative procedure is extirpation of the sac with ligature of the branch of the artery under local anaesthesia.

516 Carcinoma of the Lip

According to C. B. STEWART (*Surg., Gynecol. and Obstet.*, October, 1931, p. 533) carcinoma of the lip, though seemingly uncommon, accounts for 3 to 5 per cent. of all deaths from cancer. Its etiology is conjectural; in a few cases there is a definite history of trauma or irritation. The lower lip is more commonly affected than the upper, and males than females; in 88 cited cases, only three patients were females, and in only four was the upper lip involved. The age incidence is from 23 to 85 years, the most frequent decade being that between 50 and 60. The pathological condition ranges from sarcoma to adult cell carcinoma; nearly all cases are of the squamous-cell type. The growths may be classified into papillary and infiltrating; the former spread over considerable lip margin but give rise to metastases late. The latter are very resistant, and prone to recur; metastasis occurs early, and is extensive. The chief diagnostic points are enumerated. The disease must be differentiated from simple ulceration, leucoplakia, tuberculosis, and syphilis. Stewart states that labial epithelioma can be destroyed by radium without resulting deformity (74 cases were thus treated), but that treatment should not be restricted to any one agent. Metastases should be surgically removed when possible, and radium emanation be left in questionable areas. Inoperable nodes can be sterilized by radium implants, and advanced cases be relieved by small doses of *x* rays or radium.

517 Surgical Treatment of Pericardial Scar

Two types of operations for the treatment of adhesive pericarditis have been devised—one by Delorme for intrapericardial adhesions, the other by Bauer for the extrapericardial kind. C. S. BECK (*Journ. Amer. Med. Assoc.*, September 19th, 1931, p. 824) believes that the two pathological processes have been too sharply differentiated, and that the Bauer operation is now obsolete. Circulatory failure due to pericardial scar can, however, be wholly relieved by operation; pericardiectomy, performed as completely as is anatomically possible, is advocated as the operation of choice. A case is recorded and the operative technique is described. The operation should be carried out in one stage, since the heart will tolerate only one major intervention; if not then relieved of all mechanical impediments, it may fail to recover. It should also be performed in a negative chamber to prevent "pneumocardiac tamponade"—action of atmospheric pressure on the heart and great vessels at the cardiac base. If this risk can be eliminated by using the negative chamber, exploratory pericardiotomy can be carried out in obscure cases. In view of the relief to be obtained by operation, Beck urges the importance of recognizing circulatory disturbances due to pericardial scar.

Therapeutics

518 Value of Alkali in Salicylate Therapy

N. MORRIS and S. GRAHAM (*Arch. Dis. in Child.*, October, 1931, p. 273) are satisfied that in salicylate poisoning an acidosis is present, as is indicated by the clinical picture, the behaviour of the CO_2 content, and the response to alkali therapeusis. They find that the oral administration of sodium salicylate alone in daily doses of more than 60 grains to children results in the production of a non-gaseous acidosis, which is not due to the presence *per se* of the acid salicyl ion. In these patients there is also evidence of impaired renal function. These pathological sequels can be prevented by the exhibition of sodium bicarbonate, but glucose is ineffective in this respect. One effect of the alkali appears to be the prevention of renal damage, thus permitting the more rapid excretion of the salicylate twofold or fourfold. The failure of glucose to obviate poisoning suggests that the symptoms of salicylate overdosage are not necessarily associated with incomplete fat oxidation. As a result of their investigations the authors emphasize the value of associating the exhibition of alkalis with salicylate therapy, and mention that at the Glasgow Royal Hospital for Sick Children it has been the custom to give four-hourly doses of 15 grains of sodium salicylate (90 grains daily) with twice the amount of sodium bicarbonate. In some cases 20 grains four-hourly (120 grains daily) were given, and, even so, signs of intolerance were seldom observed. Vomiting alone occurred with any frequency, but if the bowels were kept freely open intermission of the treatment was obviated. In cases of idiosyncrasy it is advisable to start with smaller doses, and gradually increase them.

519 Vaccine Therapy in Chronic Arthritis

A. E. VIPOND (*Canadian Med. Assoc. Journ.*, October, 1931, p. 432) believes that, unless focal infection in various structures such as the teeth and tonsils is clearly indicated, surgical intervention in chronic arthritis is not justifiable. This disease, being of slow progression and long duration, should be a suitable field for specific vaccine therapy. In ten out of twelve cases here recorded, seven of which were severe, with marked articular deformity and fixation, the same species of streptococcus was isolated from the enlarged nodes. A vaccine made from this organism produced a cure or marked improvement in the symptoms and the general and local lesions. The vaccine employed contained 500 millions per c.cm. This amount was given twice or three times each week, and the dose was increased to 1.5, and finally to 2 c.cm., at which height it was kept. Reactions were either absent or very slight. Vipond maintains that, if the customary therapeutic measures are supplemented by specific vaccine therapy, the results are remarkably better; in many cases complete cure can be expected.

520 Treatment of Infantile Anaemia

The opinion is gaining ground that iron in large doses is curative in infantile secondary anaemias. H. JOSEPHS (*Bull. Johns Hopkins Hosp.*, October, 1931, p. 246) presents a study of 44 anaemic children, aged from three months to two years, who were successfully treated in three stages with iron, and iron with copper. During the first stage, a period of observation which was [illegible] omitted, no iron was administered. During the second, which also was frequently omitted, 10 per cent. solution of ferric ammonium citrate was given in daily doses of 2 c.cm. per kilo of body weight. In the third, a 0.5 per cent. solution of copper sulphate was added to the iron in half the dosage. The copper, usually divided into

two doses, was always given in milk. No disagreeable results followed, though in older children this dose may cause vomiting and diarrhoea. Blood formation may be divided into two functions—haemopoietic activity (as measured by a reticulocyte rise) and haemoglobin synthesis. Josephs states that iron given in medicinal doses stimulates haemopoietic activity; its effect is first on the reticulocytes, then on the haemoglobin—a latent period usually occurs before the latter rises. Copper appears to accelerate haemoglobin formation, being apparently a needed factor even when the haemopoietic tissue has been well stimulated; it has no effect on the reticulocytes. In the present series, the speed of recovery was unaffected by the diet, and medicinal iron was found to be far superior to iron supplied in the food in causing a rapid recovery.

Ophthalmology

521 Circulation of the Aqueous Fluid

In view of the fact that the source, volume of flow, and mode of reabsorption of the aqueous fluid is the key to the understanding of glaucoma, J. S. FRIEDENWALD and H. F. PIERCE (*Bull. Johns Hopkins Hosp.*, October, 1931, p. 259) report a series of experiments they have been conducting during the last eight years to determine what, if any, is the volume of flow; where, and by what mechanism, is the fluid formed; and where and how is it absorbed. They find that the circulatory dynamic mechanism of Schlemm's canal and its connecting venules is measurably dissociable from that of the intra-ocular capillaries; in fact, it is devised precisely to check any gross change in intra-ocular pressure being produced by alterations in the general arterial or venous pressure. The presence of proteins in the anterior chamber was shown to diminish the rate of outflow of the aqueous, but this rate was increased by congestion and vaso-dilation. The authors state that in many cases of intra-ocular inflammatory disease the intra-ocular pressure may be largely determined by the balance between these two conflicting forces. They add that the conclusions they have drawn as regards the circulation of the aqueous do not conflict in any way with the well-established facts regarding the chemical constitution of this fluid, which approximates a dialysate of the blood plasma, and tends toward thermodynamic equilibrium with the blood; this, however, in no way requires a hydrostatic equilibrium. It was not possible to distinguish chemically between an equilibrium reached by dialysis, and one resulting approximately from combined ultra-filtration and osmotic reabsorption. In the main, the barrier between the blood and the aqueous must behave as an inert semi-permeable membrane, or, when as in the ciliary epithelium the barrier is an active one, its activity must be such as to affect equally all the constituents of the aqueous.

522 Etiology of Optic Neuropathies

A. C. WOODS and W. M. ROWLAND (*Journ. Amer. Med. Assoc.*, August 8th, 1931, p. 375), in the term "neuropathy" include primary and secondary optic atrophy, retrobulbar neuritis, papillo-macular bundle atrophy, optic neuritis, and choked disk. Of 138 neuropathies 27 per cent. were due to intracranial tumour; 5.1 per cent. to pseudo-tumour (mainly arachnoiditis); 16 per cent. to syphilis of the central nervous system; 0.7 per cent. to secondary syphilis; 10.9 per cent. to arterio-sclerosis; 8.1 per cent. to posterior sinus disease; 6.5 per cent. to multiple sclerosis; 2.9 per cent. to focal infection; 4.4 per cent. to toxic amblyopia; 1.5 per cent. to Leber's disease; 1.5 per cent. associated with mental retardation but with no pathological factor; 1.5 per cent. to intracranial aneurysm; 5.1 per cent. to miscellaneous conditions; and 8.1 per cent. undetermined. Of the intracranial group 37 per cent. were pituitary tumours; one of these patients had primary optic atrophy in one eye, and choked disk in the other. One case of cerebral tumour was accompanied by primary optic atrophy. All those with pineal tumours had oculomotor involvement. In view of the recent controversy about the relative etiological importance of multiple sclerosis and posterior sinus disease, it is interesting to note the percentage incidence of these two groups in the above table. The authors believe that the figures given are too high for intracranial tumour, and too low for syphilis.

523 Shortening Operations in Concomitant Squint

L. C. PETER (*Arch. of Ophthalmol.*, September, 1931, p. 380) states that defective fusion faculty forms the predisposing, and errors of refraction or other factors the determining, cause. While central vision can be restored at the age of 6, and fusion at 7, all forms of treatment give the best results before the age of 6. Peter describes tendon-tucking (giving a correction of 10–15 degrees) as being more applicable to heterophoria; 00 ten-day catgut should be used. He advises resection (Reese), and or advancement (Worth), for the best end-results. Resection gives 10–15 degrees, and advancement 15–25 degrees of correction. Pure tenotomy is not advisable, and recession should not reduce convergence beyond the requirements of sustained near work. A convergent squint of 10 degrees calls for resection or tucking; of 15 degrees, resection or possibly advancement; of 20 degrees, advancement with perhaps recession; of 25–30 degrees, double advancement or advancement and recession; and of 30 degrees or more, double advancement with single or double recession. The same procedures are 30–40 per cent. less effective in divergent squint.

524 Treatment of Retinal Detachment

L. COPPEZ (*Le Scalpel*, July 25th, 1931, p. 925) reviews the various ineffectual forms of treatment of idiopathic retinal detachment which preceded the advent of Gonin's technique. Medical treatment included complete rest, compression bandages, induction of sweating of the scalp, insistence on a salt-free diet, and the employment of subconjunctival injections. Surgical treatment comprised simple sclerotic puncture; puncture, with aspiration of the subretinal fluid; trephining; cauterization; incisions of the vitreous; and injections of subretinal or other fluids into the vitreous. Gonin believes that detachment follows the formation of a hole or holes in the retina, which, though always present, and sometimes far removed from the site of the detachment, may require many examinations before being detected. The distance of the tear from the ora serrata in disk-diameters, and its meridian, must be accurately determined before an operation is undertaken. Cases unfavourable for operation are those with a long history, with very large, posterior, or multiple holes, and with large separations at the ora serrata. Favourable cases have a short history, and a single, well-marked, accessible hole. Gonin reported 50 per cent. of cures in favourable, and 10 per cent. in unfavourable cases; Coppez states now that he has had similar results from using Gonin's technique.

Obstetrics and Gynaecology

525 Late Effects of Pregnancy Toxaemias

C. H. PECKHAM and M. L. STOUT (*Bull. Johns Hopkins Hosp.*, October, 1931, p. 225) record a study of the late effects of the toxaemias, excluding vomiting and eclampsia, based on a series of 545 consecutive deliveries of toxaemic patients. Of these, 343 were examined four months to four years after delivery, and definite chronic nephritis was found in 40 per cent. This sequel appeared more frequently in the older age groups, and among multiparae; two-thirds of the cases of non-nephritic toxaemia were in women under the age of 25, and two-thirds were primiparae. Marked hypertension (systolic reading 200 mm. or more, and diastolic 150 mm. or more) was more frequently associated with nephritis, though an occasional case of pre-eclampsia was found with such a reading. Neither albuminuria nor the presence or absence of casts

In the urine had prognostic significance. The blood pressure is higher on discharge in the nephritic type as a rule, but many women who have nephritis leave hospital with a normal blood pressure. Even as late as six weeks after delivery many normal women still have hypertension and albuminuria, while a few nephritic patients appear to be normal in these respects. Almost one-fifth of the women who were ultimately diagnosed as nephritic were known to be normal until after the seventh month ; this would seem to indicate that chronic renal damage may be a result of the toxaemic process. The authors conclude that, excluding vomiting and eclampsia, one out of every three women seen with a toxaemia of pregnancy will be found ultimately to have nephritis. Except in perfectly obvious cases it seems better to defer the final diagnosis until four months after delivery, although a diagnosis intelligently made at the time of discharge from hospital is only incorrect in one case out of nine.

526 Acute Haemorrhage from Myoma of the Cervix

G. FROMMOLT (*Zentralbl. f. Gynäk.*, October 3rd, 1931, p. 2951) describes the case of a 2-para, aged 33, whose menses were somewhat profuse, but in whom a pelvic tumour was believed to be the uterus of six months' pregnancy. Subsequently a large cervical myoma was recognized ; the contemplated hysterectomy had to be performed urgently in consequence of a profuse haemorrhage (the first), which led within twenty-four hours to extreme collapse. The bleeding was found to have come from a ruptured vein on the intrauterine surface of the myoma, not far from the internal os.

527 Treatment of Ureteral Fistula

According to F. MONTUORO (*Riv. d'Ostet. e Ginecol. Prat.*, September, 1931, p. 371) unfavourable opinions which have lately been expressed concerning the utility of uretero-cystostomy in treatment of ureteral fistula are not altogether justified. It is true that such operations, performed a generation ago, were followed by stenosis at the anastomosis, but, as Rinaldi has recently pointed out, the operation demands consideration of the clinical as well as of the hydraulic circumstances. It is useless where the renal function on the affected side is already impaired by infection or otherwise, but, undertaken early (the kidney function having been proved to be still sound), it has led to five to ten years' survival, with persistence of function both of the kidney and of the stoma. These results have been obtained by Italian surgeons ; they adopt the Boari technique—transperitoneal approach, and extraperitoneal uretero-cystostomy in which a metal button is used.

Pathology

528 The Permeability of the Meningeal Barrier

G. RAMON and P. DESCOMBEY (*C. R. Soc. de Biologie*, October 23rd, 1931, p. 358) immunized horses with tetanus or diphtheria anatoxin ; they then tested the antitoxin content of the blood serum and, at the same time, of the cerebro-spinal fluid. Antitoxin was always found in the cerebro-spinal fluid, but as a rule only in about one-hundredth the amount of that in the serum. Experiments in rabbits showed that only about 1/10,000 of the quantity of antitoxin passed into the cerebro-spinal fluid. In the dog, according to Debré and Lemaire, the relation of the serum to the spinal fluid antitoxin is about 1 to 500. Working with horses the authors tested the permeability of the meninges to tetanus toxin itself. By the intravenous route 40 c.cm. of toxin were injected into a horse, and two days later, when the first symptoms of tetanus became evident, the amount of toxin in the blood and in the spinal fluid was tested by guinea-pig inoculation. It was found that 0.1 c.cm. of serum and 10 c.cm. of spinal fluid were fatal. The ratio of toxicity was therefore 100 to 1, the same ratio in fact as was found with antitoxin. The meningeal barrier prevents in large measure the passage of proteins from the blood to the subarachnoid space ; it has very little effect in the opposite direction. Rabbits injected with tetanus toxin or antitoxin into the subarachnoid space were bled a few hours later ; the greater part of the toxin or antitoxin was found in the blood.

529 Methylene Blue as a Test for Bilirubin

According to Franke, methylene blue is a sensitive reagent for the presence of bilirubin ; the test is performed by dropping a 0.2 per cent. watery solution into 5 c.cm. urine. In the presence of bilirubin a green colour is produced, and the number of drops necessary before this turns to blue affords a rough indication of the amount of bilirubin present. J. SEIDE and K. ZINK (*Deut. med. Woch.*, October 9th, 1931, p. 1744) report the results of a series of tests on 100 urines. A result of more than 10 drops is recorded as strongly positive, 2 to 10 drops weakly positive, and 1 drop negative. They found a strongly positive reaction in all liver conditions associated with jaundice, including catarrhal jaundice, syphilis, carcinoma and cirrhosis of the liver, and severe congestion. Weakly positive reactions occurred in pernicious anaemia, lead poisoning, malaria, cholelithiasis, influenza, and slighter cases of congestion. The tests were all controlled by the iodine reaction, which was found to be not nearly so sensitive. The methylene blue test thus appears to be a delicate test for minor degrees of jaundice, and liver disease, and can be used in a roughly quantitative manner to follow the course of the illness. There are fallacies in the case of blood-stained urines, and in patients who have received the anthraquinone group of drugs. A patient with nephrolithiasis, who had been treated with trypaflavine, also gave a weakly positive reaction. The nature of the test is discussed ; it appears to be largely a case of colour mixture, but may depend to some extent on the oxidation of bilirubin.

530 Fat Atrophy following Insulin Injections

J. R. WILLIAMS (*Journ. Lab. and Clin. Med.*, September, 1931, p. 1191) maintains that patients receiving insulin treatment should be frequently examined. When one site (most commonly the thigh) is repeatedly injected, the sense of pain is lost, and untoward effects may be produced. A case is recorded in which marked atrophy of the subcutaneous fat on both thighs ensued after insulin injections. The atrophy disappeared, being replaced by fresh fat, when new areas for each injection were employed. The cause of this atrophy is unknown. Fischer and Rabinowitch suggest that the insulin may injure the covering membrane of the fat cells, thus releasing the fat globules ; these act as foreign bodies, and result in the formation of histocytes which assume lipophagic activity. Possibly, a low-grade inflammation, due to the repeated injections, may cause a disappearance of the soft alveolar tissue, and its subsequent replacement by scar tissue. Nerve injury with consequent atrophy is another possibility. Williams emphasizes the necessity of admonishing patients about constantly changing the injection site. He doubts the wisdom of permitting untrained diabetics to use insulin.

531 Endemic Typhus and the Rat Flea

H. A. KEMP (*Journ. Amer. Med. Assoc.*, September 12th, 1931, p. 775) alludes to the view maintained by Maxcy, Shelmire and Dove, and Dyer, Rumreich, and Badger, that endemic or New World typhus is transmitted by the rat flea, and records the following experiments. Guinea-pigs, inoculated with fleas removed from rats which had been trapped at a typhus focus, developed lesions characteristic of endemic typhus. The animals which had recovered from an attack produced by this virus were found to be immune to a strain of typhus virus, obtained from the blood of a human patient with endemic typhus. Likewise, animals which were immune to blood virus were also immune to the strain of rat flea virus obtained by guinea-pig inoculations.

de KUYPER'S

HOLLANDS

Distilled from genuine malt liquor with the Juniper berry added. The advantage gained by distilling the berry with the spirit is the production of a preparation of Oleum Juniperi, mellow and free from irritating properties.

Oleum Juniperi is official in the British Pharmacopoeia, and is described as carminative, anti-spasmodic, and a stimulating diuretic.

In this form, therefore, the oil of Juniper can be safely taken with regularity.

Distilled by the same family for 236 years.

FELAMINE BRAND SANDOZ

SANDOZ

An association of the most powerful cholagogue—pure crystallised cholic acid—and the classical biliary disinfectant—hexamine, entirely free from accessory substances.

Indications:

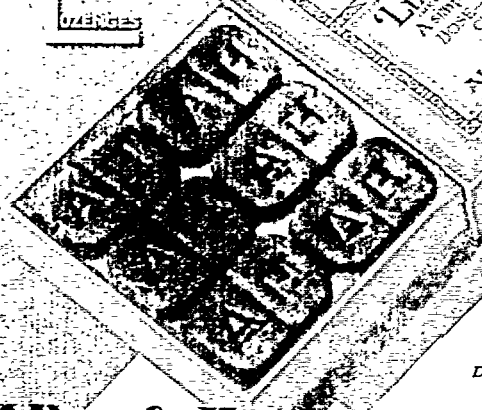
CHOLANGITIS, CHOLECYSTITIS, HEPATIC INSUFFICIENCY, HEPATIC CONGESTION, JAUNDICE, CHRONIC CONSTIPATION.

Felamine is supplied in Bottles of 50 and 250 Tablets.

AGENCY:-
SANDOZ CHEMICAL WORKS PHARMACEUTICAL DEPT.
5, WIGMORE STREET, LONDON.W.1.

Alternative Methods in Prophylaxis and Treatment of

CORYZA



DETOXICATED ANTI-CORYZA VACCINE. This Vaccine has been used with great success for several years. Its outstanding feature is the absence of reaction, which makes it especially useful for hyper-sensitive patients.

ORDINARY ANTI-CORYZA VACCINE. Some Practitioners consider that a slight reaction has definite therapeutic value, and this type of Vaccine has been prepared to meet their requirements. It has the advantage of very low price.

ANTI-CORYZA VACCINE SPRAY (For local application to the nose and throat). For patients who object to Vaccine treatment by subcutaneous injection, and for children, this Local Immunity Product is particularly indicated. An additional convenience is that frequent attendances by the patient for injections are unnecessary.

Additional information regarding the above products will gladly be supplied to any Practitioner who writes to The Vaccine Department, Genatosan Ltd., Loughborough, Leicestershire.

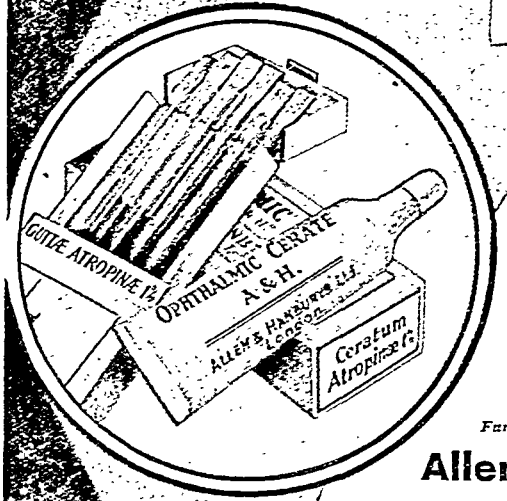
A Non-Griping and Palatable Preparation of Senna

Contain "Lixen" in a fruit basis.

Really pleasant to take.

Appeal particularly to children.

Each lozenge is equivalent to 6 large senna pods.



In boxes of 12 and 24 lozenges for prescribing.
In bottles of 100 lozenges for dispensing.

Descriptive literature and clinical trial sample will be sent on request.

Allen & Hanburys Ltd., London, E.2.

Telephone: 3001 Bishopsgate (10 lines) *Telegrams:* "Greenburys Beth London"

Ophthalmic Products "A. & H."

Prepared in accordance with the latest scientific methods.

Highest degree of activity and stability ensured.

The series of Cerates and Drops comprises most of the agents used in everyday practice.

Any special formula can be prepared.

Further particulars and supplies are obtainable from

Allen & Hanburys Ltd.
London, E.2

ARTERIOSCLEROSIS

KAYLENE-OL

A LETTER RECENTLY RECEIVED:

"I have recently been consulted by a man who suffered from severe pain and wasting of the muscles of his right upper arm, due to partial occlusion of the corresponding arteries. The trouble had commenced two years previously. His brachial arteries were very tortuous and hardened, obviously in a condition of advanced arteriosclerosis. There was not much hyperpiesis, his systolic blood pressure being 152 mm. and his diastolic 98.

"Massage, whirlpool baths, heat, electricity and drugs had been tried in a number of forms but the condition had gone from bad to worse until he was totally unable to carry on with his work as a mechanic. Although he was not constipated, Kaylene-ol was prescribed with startling success. The pain began to lessen after two weeks, and at the end of a month not only was he entirely free from pain but the muscle had filled out until there was very little difference between the two arms. His right upper arm fully flexed measured 30 cms. in circumference and his left 31 cms.

"Just before starting Kaylene-ol he was too weak to lift a cup of tea with the right hand, and to use his own words he now 'could lift a table.'

"I have seen many similar cases in which cramps and muscle pains of vascular origin have disappeared quickly after prescribing Kaylene in some form, but I have never before seen such a dramatic improvement in the nutrition of the muscles concerned."

.....M.D., F.R.C.P.

"Adsorption" literature, and supplies for clinical trial forwarded on request to:—

KAYLENE LIMITED,
WATERLOO ROAD, LONDON, N.W.2

STANIFORM

Regd BRAND Trade Mark.

METHYL STANNIC IODIDE

OINTMENT
Immediately stops the pain in all cases of burns, scalds, etc

DUSTING POWDER
For application where a greasy substance is counter-indicated

LINIMENT
Remarkably effective in treatment of Rheumatoid Arthritis

LOTION
A panacea for Mosquito and other insect bites Most effective for all purposes where Tr Iodine is employed Does not stain the skin and there is no sting

TABLETS
Staniform being an organic compound is more easily assimilated than the Tin preparations at present in use

Supplies may be obtained through the Wholesale Druggists, Dispensing Chemists' Sundriesmen, or Dental Supply Companies

What the Profession says

The following are three recent unsolicited testimonials reported to the Manufacturers by Medical Men

"I continue to get every satisfaction from 'Staniform' in the case of carbuncles, boils, whitlows, and, in fact, all kinds of infected wounds"

"In a case of acute eczema on leg, the skin was quite normal within one week after starting applications of 'Staniform'"

"In a case of an abrasion with large scab the ointment was tried and found very effective Scab came away very quickly and healing was very clean and satisfactory"

Similar testimony has been received from a large number of medical men when "Staniform" has been used for the treatment of Burns, Wounds, and Skin Ailments

STANIFORM is used in Leading Hospitals.

STANIFORM over a wide field of clinical experience has exhibited [illegible] curative properties Combining the well known usefulness of Tin in [illegible] coccic infections with the powerful germicidal properties of Iodine [illegible] is indicated generally in local inflammations, inducing an immediate effect with rapid healing"

STANIFORM LTD., CARNWATH ROAD, LONDON, S.W.6

NOVOCAIN

The Original Preparation
English Trade Mark No. 276477 (1905)

The Safest Local Anaesthetic for all Surgical Cases.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify "Novocain" for your next operation.
Does not contain Cocaine, and does not come under the Dangerous Drugs Act.
WRITE FOR LITERATURE.

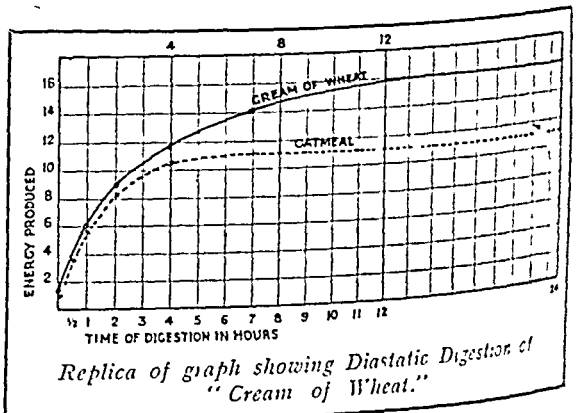
Distributing Agents:—SANGERS LTD., 258, Euston Road, London, N.W.1.

50% higher sugar yield

"After four hours the digestion of Oatmeal was at a standstill, while that of 'Cream of Wheat' continued for a further four"

THE paramount importance of starch in infant feeding, even as early as the 3rd month, is universally recognised to-day.

Four outstanding advantages of its introduction are acknowledged to be:



Slower carbohydrate digestion.
Prevention of fermentative diarrhoea.
Thorough metabolization of fat.
Retarded curd formation.

The results given opposite of experiments with "Cream of Wheat" by a leading Biochemical Institute are therefore of unique interest. The general consensus of opinion in favour of a wheat cereal, compared with oats, makes them doubly so.

* Leading paediatrists put "Cream of Wheat" on their diet sheets both as a first solid food for infants and for children suffering from fat intolerance.

It consists entirely of the granulated endosperm of the best hard wheat and contains no harsh parts.

On receipt of a professional card full details of the above tests and a sample of "Cream of Wheat" will be sent. Dept. W13, Fassett & Johnson Limited, 86, Clerkenwell Road, London, E.C.1.

Replica of graph showing Diastatic Digestion of "Cream of Wheat."

1. The starches of "Cream of Wheat" were more rapidly converted into sugar.
2. After 4 hours the digestion of oatmeal was practically at a standstill while digestion of "Cream of Wheat" continued at a scarcely diminished rate for a further 4 hours or so.
3. When digestion was complete the amount of sugar from "Cream of Wheat" was nearly half as much again as that obtained from oatmeal.

"CREAM of WHEAT"

* "*Modern Methods of Feeding in Infancy and Childhood*." DONALD PATERSON, B.A., M.D (Edin.), M.R.C.P.(Lond.), and J. FOREST SMITH, M.R.C.P.(Lond.). Pp. 84, 85, 86, and 111. (Publishers, Constable; 1929.)

* "*Modern Infant-Feeding*." BERNARD MYERS, C.M.G., M.D., M.R.C.P. Pp. 90. (Publishers, Cape; 1930.)

* "*Diseases of Children*." Sir ARCHIBALD E. GARROD, K.C.M.G., D.M., M.A., F.R.C.P., F.R.S., the late FREDERICK E. BATTEN, M.D., M.A., F.R.C.P., and HUGH THURSFIELD, D.M., M.A., F.R.C.P. Pp. 69, 70, and 71. (Publishers, Edward Arnold & Co; 1929.)

And many others.

A safe and simple antacid which is also a gentle laxative must necessarily be of great value to medical practitioners when administering to ladies and children and all who are constitutionally delicate.

May we, therefore, venture to remind you of

DINNEFORD'S PURE FLUID MAGNESIA

which has been extensively prescribed and used by the Medical Profession for a Century, and is still the best and safest means of administering Magnesia.

When prescribed for the nursery, too, Dinneford's Magnesia has always proved immensely useful as a corrective, and when mixed with infant's food it prevents many of the troubles which are due to acidity, flatulence, etc.

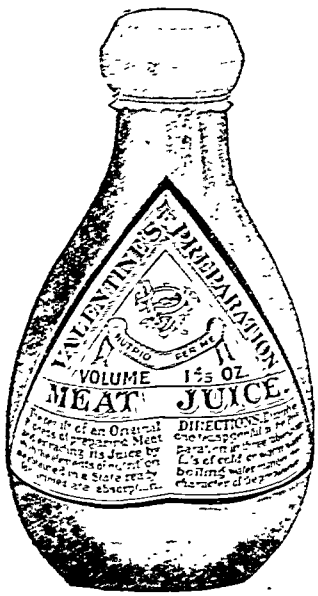
We are confident that you will find in Dinneford's Fluid Magnesia a reliable and safe solution which may be freely used for many ailments, and we would request your kind consideration of its use as occasion offers.

Dinneford's Pure Fluid Magnesia possesses antacid and laxative qualities which are incomparably better than those of any of the various preparations of Magnesia, in powder, now being introduced.

It cannot harm the most delicate constitution and is at all times a safe and effective laxative.

Manufactured in London for the past 100 years.

DINNEFORD & Co. LTD.



Valentine's Meat-Juice

IN the Treatment of Weak Babies, in the Gastric and Enteric Troubles of Infants and in the Wasting and Febrile Diseases of Children, the Ease of Assimilation and Power of Valentine's Meat-Juice to Sustain and Strengthen has been Demonstrated in

Hospitals for Children.

The quickness and power with which Valentine's Meat-Juice acts, the manner in which it adapts itself to and quiets the irritable stomach, its agreeable taste, ease of administration and entire assimilation recommend it to physician and patient.

Physicians are invited to send for Clinical Reports.

For sale by European and American Chemists and Druggists.

EVANS' THROAT Pastilles

ENTIRELY BRITISH MADE BY

EVANS SONS LESCHER & WEBB Ltd.

56, Hanover Street, LIVERPOOL
50, Bartholomew Close, LONDON

THROAT THERAPY

Evans' Pastilles are prepared to a formula of the Liverpool Throat Hospital. Their action is soothing and demulcent, the formula being carefully balanced with both these objects in view. Evans' Pastilles relieve harshness and irritation and maintain their effect for some time after the pastille has dissolved.

Sold in 1/- tins or in bulk for dispensing.

We will send with pleasure a physician's sample on request.

Nutritional anaemia in infancy

IT has recently been shown that breast milk does not contain an adequate amount of iron and that from the early days of infancy it is necessary to supply iron to the organism, if healthy development of the child is to be attained.

The organic iron in Virol from Glycerine Extract of Red Bone Marrow and from yolk of eggs is absorbed with ease.

The vitamin-containing Fats are very finely emulsified; they are therefore, easily digested by the most sensitive alimentary tract at all ages, including earliest infancy.

All experience goes to show that Virol is a food of marked value in a great variety of conditions in which adequate nutrition by ordinary means is not easy to secure.

VIROL

Mineral salts : vitamins : balance : digestibility

Virol is sold in Jars at 1 3, 2 - & 3 9, 1-gall 15 - - - - - Virol, Ltd., Ealing, London, W 5.

RHEUMATISM

Osteo and Rheumatoid Arthritis alike respond readily to treatment by Arthritone. For over a decade it has been used by practitioners throughout the country, with consistently good results, and in many cases after all other forms of medication had proved of no avail.

HEXYL-RESORCINOL (BOOTS)

TESTED by the usual Rideal Walker method, HEXYL-RESORCINOL—BOOTS, is shown to possess a co-efficient 100 times greater than Phenol and therefore very much greater than that of the ordinary organic disinfectants in general use. At the same time, the prescribed dose has no toxic action towards man or animals.

HEXYL-RESORCINOL—BOOTS, is supplied in Enteric-coated Tablets—in bottles of 25 and 100 tablets. Special Gelatin Capsules—in boxes of 24 and 100 capsules—are also available.

Thyroid Medication

A new preparation of the pioneers in endocrine therapy

The name given to Reed & Carnrick's new thyroid speciality is Thyracoids.
"Thyracoids" consist of iodo-thyroglobulin, standardised biologically. They can be depended upon to be of uniform strength and to represent the entire activity of desiccated thyroid.
Thyracoids may be used advantageously in all cases where thyroid medication is indicated.

Packings: Bottles of 100 $\frac{1}{10}$, $\frac{1}{4}$, 1 and 2 grain tablets
Plain or enteric coated.

Descriptive literature from Sole Distributing Agents for U.K. and Irish Free State.
COATES & COOPER, LTD.
94, Clerkenwell Road, E.C.1.

Thyracoids

Manufactured by REED & CARNRICK, Pioneers in Endocrine Therapy, Jersey City, NEW JERSEY.

It is Significant that so many of the Medical Profession when prescribing "Liquor Carbonis Detergens" add the word

Wright's

Although there is no secrecy as to the composition of Liquor Carbonis Detergens (it is described as "an alcoholic solution of coal tar"), the method of manufacture is unique. Imitations will be found to be produced by simple digestion, usually accompanied by some primitive, perfunctory, and inadequate stirring; whereas, in the case of the genuine product, the intimate contact required for the complete extraction of all the soluble antiseptic constituents is attained by a series of complicated processes involving the use of highly specialized machinery.

On receipt of your professional card, a package will be sent containing a sample of each of the following—

Wright's Coal Tar Soap.
Wright's Coal Tar Ointment.
Wright's Lysol.
Wright's Liquor Carbonis Detergens.

WRIGHT, LAYMAN & UMNEY LTD., 66, Park St., Southwark, S.E.1.

DYSPEPSIA AFTER TEA

This is the action of the tear tha-t is "Ty-phoo"

To prove that "Ty-phoo" natural leaf-edge tea is valuable in various forms of indigestion we print below one of the testimonials which we are constantly receiving from medical men.

"I have found Ty-phoo tea most useful in treating dyspepsia, and many of my patients can take no other tea. Time after time I have found on trying to leave it off I have had to go back to its use. It has been very marked to me the persistent pain I have suffered while taking Indian tea which has been absolutely removed on returning to Ty-phoo."

—, Esq., M.D., No. 0209.

A Physician writes:

(Over 12,500 Doctors are upon our books as direct buyers from us)

SOMNIGEN

The advantage of "Somnigen" is that it does not produce the Headache, Nausea, Furred Tongue, or Constipation so frequently noticed when preparations of Opium or Morphine are administered. It contains the whole of the Alkaloids of Opium in chemical combination with Hydrobromic Acid, which assists the sedative action, and is STANDARDISED so as to contain 0·75 per cent Morphine, but entirely free from nauseous odour and characteristic taste.

As an Hypnotic, Sedative, Opiate and Diaphoretic it has always given great satisfaction, as its action is most regular and certain, producing refreshing sleep without unpleasant after-effects.

"It is free from the odour of the ordinary Tincture of Opium, and does not produce the same disagreeable after effect."
—THE MEDICAL ANNUAL

"It has the advantage of not being followed by nausea and headache and other drawbacks of Laudanum."
—THE INDIAN MEDICAL GAZETTE.

THE DOSE IS 5 TO 40 MINIMS

PRICE in England, 12/6 per lb. Packed in 5-oz., 10-oz., 22-oz., 40-oz., and 90-oz. Bottles.

C. J. HEWLETT & SON, Ltd., 35 to 42, CHARLOTTE STREET, LONDON, E.C.2.

'NEOTROPIN'

Urinary antiseptic and general internal disinfectant.

The remarkable power of penetration is a fundamental factor of its effectiveness.

SCHERING LTD., 3, Lloyd's Avenue, London, E.C.3.

Beefex

THE CONCENTRATED BEEF EXTRACT

Beefex is genuine Beef Extract—the flavour is pleasant and not unduly saline. It can conscientiously be recommended as a nutritious and stimulating beverage for use during illness. May we send you a sample bottle?

Medical men should apply to:

BEEFEX LTD., BEEFEX HOUSE, LONDON, E.C.1.

I'm a Beefexer! —Beefexers are the modern Beefeaters who like their rich prime Beef in beverage form. A cup of Beefex every night and every morning keeps me fit.

INSULIN 'A.B.'

The world-wide supremacy of Insulin 'A.B.' is due to its unequivocal purity no less than to its well-known potency and stability under all conditions.

Insulin 'A.B.' contains the minute quantity of phenolic preservative originally recommended by the Medical Research Council and still considered necessary by bacteriologists (*Lancet*, Sept. 12, 1931, pp. 582-584) as a complete safeguard against the development of bacteria that may be accidentally introduced during self-administration.

Supplied in three strengths
20, 40 and 80 units per c.c.

Full particulars and the latest literature will be sent free to members of the Medical Profession.

Joint Licencees and Manufacturers:
The British Drug Houses Ltd. Allen & Hanburys Ltd.

FOR INTERNAL TREATMENT OF
GONORRHOEA, URETHRITIS AND OTHER AFFECTIONS
OF THE GENITO-URINARY TRACT

SANTAL MIDY CAPSULES have been prescribed with uniform success for over thirty years. Distilled from carefully selected Mysore Sandal-Wood, the oil is bland and remarkably **FREE FROM THE IRRITANT AND NAUSEATING EFFECTS** which are provoked by many preparations.

There is marked absence of gastric and other disturbances, diarrhœa and skin eruptions. Its mild chemotactic properties permits its administration in relatively large doses without ...ar of too violent reaction or intolerance.

SANTAL MIDY CAPSULES may be prescribed and relied ...ion in all stages of Gonorrhœa and in other forms of Urethritis and affections of the Genito-Urinary tract.

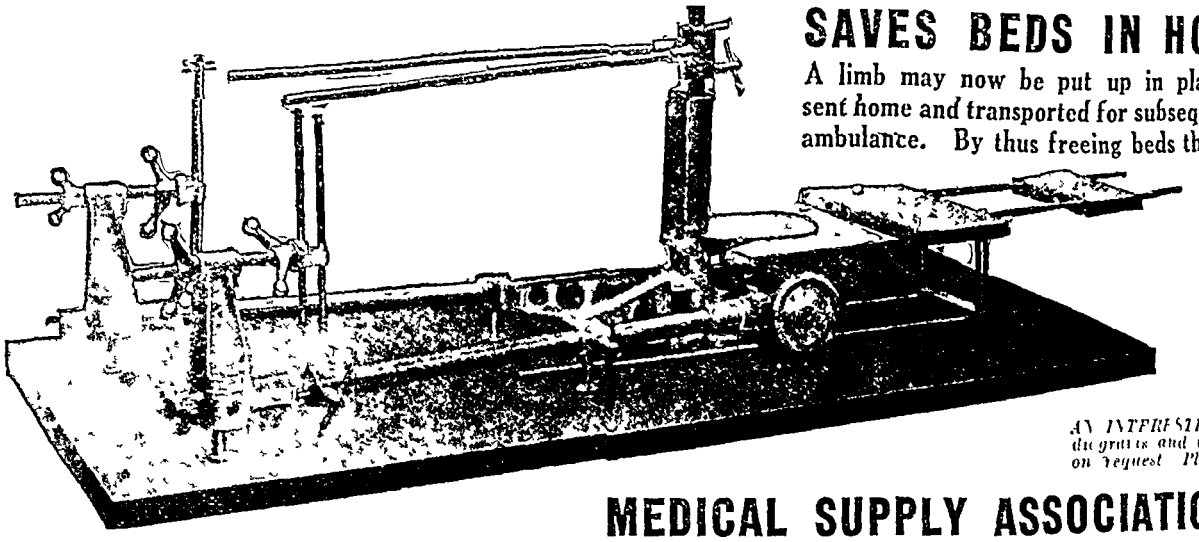
The Capsules contain 5 drops, and usually 10 to 12 are given daily in divided doses.

Prepared in the Laboratoire de Pharmacologie Generale, 8, Rue Vivienne, Paris, and sold by most Chemists and Wholesale Druggists throughout the World

U.K. Agents: WILCOX, JOZEAU & Co., 15, Gt. St. Andrew St., W.C.2.

A·K

SANTAL MIDY



An IMPROVED and MODIFIED

Portable Traction Apparatus

An exceedingly efficient and convenient apparatus for putting up in plaster the lower limbs or trunk; also when applying bone plates or Parham and Martin's Bands to long bones of the lower extremity. Provides the more essential movements of expensive and bulky Orthopaedic tables at a fraction of the cost.

Quickly adaptable for the following positions

Extension of whole lower limbs.
Movements about hip-joint.
Abduction to any degree—
Hyperextension—Flexion—
Internal and External Rotation.
Flexion of knee-joint
Inversion and Eversion of foot.

SAVES BEDS IN HOSPITALS

A limb may now be put up in plaster, the patient sent home and transported for subsequent treatment by ambulance. By thus freeing beds this new apparatus saves its cost many times over.

Folds compactly for storage or transit in plywood case 35in. X 15in. X 11in.

"CEREBAN" ADHESIVE AND SELF-SUPPORTING Bandage

SPECIALLY PREPARED FOR THE TREATMENT OF SPRAINS, DISLOCATIONS, CONTUSIONS, SWELLINGS, VARICOSE VEINS, VARICOSE ULCERS, etc., etc.

"CEREBAN" is a resin-impregnated Bandage, spread on extensible material, free from rubber and possessing elastic properties. When carefully applied it gives substantial and firm support. Porous, adhesive, and non-irritating. Experience has proved that "Cereban" Bandages are particularly suitable as a protective after-care treatment in the healing of Varicose Ulcers, etc.

"Cereban" offers many advantages over the old-fashioned Elastic Stockings or Plain Crepe Bandages ... leading to speedier recovery.

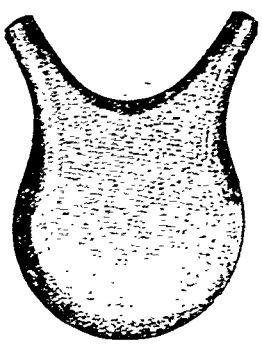
WATSON BAKER COMPANY, WEST END LANE, BARNET, HERTS, ENGLAND



MINCHIN'S CHESTPIECES

(REGISTERED)

For Single and Binaural Stethoscopes.

Being set at right angles to those in general use afford the following advantages: Time is saved, as little undressing is necessary. Bed patients can be examined without disturbance. The heart can be examined whilst patient lies face down, with the result that sounds are much more distinct. This also applies to the Foetal Heart. Children can be more readily examined by this Chestpiece than by the older patterns as it is not necessary to stand in front of them. Also made with attachment for use with Sphygmometer.

To be obtained from all Surgical Instrument Makers.

FOR more than seventy years Londoners have faithfully reckoned the hour by the chimes of Big Ben, the famous clock in the tower of the Houses of Parliament.

By the same token of esteem, physicians who first used the *Tycos* back in 1908 still depend upon it for accurate determination of blood-pressure. Although minor improvements have been made, the *Tycos* today is fundamentally the same instrument, because the mechanical principle of its construction has always been scientifically correct.

The *Tycos* was introduced to correct grave sources of error in taking blood-pressure: the oscillating mercury column, on the one hand, or the lagging column, on the other. Years of clinical use have amply proved that the rugged, thoroughly seasoned diaphragm chamber of uniform elasticity, which forms the "heart" of the *Tycos*, can be depended upon to measure slight variations of pressure with absolute accuracy.

When you take blood-pressure with the *Tycos* Sphygmomanometer, you know the reading is correct. This instrument has stood the test of time

Obtainable from all reputable instrument dealers.

Accept No Substitute for *Tycos* Accuracy

A NON-HABIT FORMING ELIMINANT

Sal Hepatica possesses all the essential qualities of the perfect purgative. Its action is prompt, painless and thorough. It is non-habit-forming, because it contains sodium phosphate which increases bile secretion—thereby avoiding the habit-forming propensities of other laxatives that call for steadily increasing doses. The exhibition of Sal Hepatica is by far the most pleasant and effective means of eliminating all toxic amino acids from your patient's system and ensuring regular defecation. Sal Hepatica is an efficient eliminant, antacid, cholagogue and duiretic.

Samples for clinical trial will be forwarded on request to duly qualified members of the medical profession on application to Bristol Myers Co.

Sal Hepatica contains sodium sulphate, sodium phosphate, sodium chloride and lithia citrate in an effervescent medium.

Sal Hepatica

the proved, medicinal, saline laxative & cholagogue.

MEMBER'S STATEMENT:

Gloucestershire,
7th May, 1931.

Dear Sir,

Enclosed please find cheque for Subscription due to the Society. I received a cheque from Mrs. C—— for £10-18-0 this morning and have forwarded a receipt to her.

THE ABOVE MEMBER SENT HIS LIST OF DEBTS TO US ON THE 5th MAY, 1931. WE THINK THIS SPEAKS FOR ITSELF.

FOR DEAFNESS

Doctors prefer "ARDENTE" because—

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises, giving inconspicuous hearing.
4. It conveys sound from varying ranges and angles.
5. It is entirely different, uncopyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf through various causes.
7. It is helpful for conversation, music, talkies, wireless, home, office, public work, and sports.
8. A wide range—electrical and non-electrical.

FREE HOME TESTS arranged for Doctors and Patients. *Medical Prescriptions made up to the minutest detail.*

"ARDENTE" STETHOSCOPE.

Mr R H Dent makes a Stethoscope specially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, as evidenced by the interest shown at the last B.M.A Meeting

MEDICAL REPORTS

Commended by all leading medical journals.—Mr. R. H. Dent will be happy to send full particulars and reprints on request, and also arrange demonstrations

Supplied in bottles at 8d., 1/3, 2/3 and 4/- each

IS IT FAIR to your best friend to make him your Executor? The duties are onerous, and usually thankless; the responsibilities are great and the penalties for neglect are severe. Moreover, he may die, and the expense of appointing his successor is considerable. On the other hand, if you appoint the Westminster Bank instead, the fees (which are paid out of your estate) will probably be only a fraction of the legacy which you would have left to a private trustee

Ask for the 'Executor and Trustee' booklet at any local branch, or call at

Genial Heat for Chilly Days

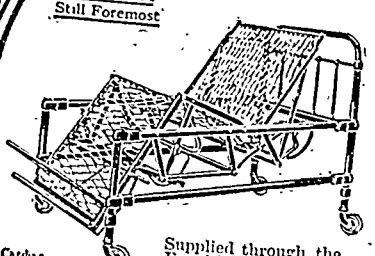
Facts about THE TILLEY RADIATOR

Height 16½ in.

Doctors' reception and consulting rooms, surgeries and hospital waiting rooms, are quickly and pleasantly warmed by the TILLEY RADIATOR at a cost of but **one penny for six hours.** It burns paraffin and requires neither connections nor fixing. **British all through.**

THE TILLEY RADIATOR

can be carried by the handle and used for heating reception or consulting room, living room, bedroom, or nursery, so that the *Radiator provides warmth when and where you need it, at less than a tenth of the cost of electricity.* Absolutely safe and cannot explode. No wick to adjust, and causes neither smoke, smell, nor mess. Reflector is made of polished copper; the mantle is strong and lasts well.



The price of the Tilley Radiator as illustrated is 45/-. Enquire Local Ironmonger. If any difficulty, Radiator will be sent post free on receipt of remittance, or C.O.D., post and charges paid.

For large rooms, we make a Radiator with two burners—twice the heat—write for particulars. Lamps for the home also supplied.

ON most of the occasions when you find it especially necessary to recommend woollen underwear it is a serious matter and worth a little serious thought. To carry the suggestion a step further and say not only wool but Wolsey is a piece of discretion, for Wolsey Underwear has long been known as the finest and healthiest woollen underwear made. Scientific investigations* have proved that garments made of wool do more than any other to prevent the deposition of moisture on the skin; retain warmth better than any other material, and allow the most equable body temperature possible. Such is Wolsey.

* *By the British Research Association for the Woollen and Worsted Industries, detailed reports of which will be sent free on application to Wolsey Ltd., Leicester.*

ST. ANDREW'S HOSPITAL

FOR MENTAL DISORDERS,

NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or who wish to prevent recurrent attacks of mental trouble, temporary patients, and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms, with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

THE COPPICE, NOTTINGHAM.

HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary and Temporary Patients received.

Tel.: 64117. *For terms, etc., apply to the Medical Superintendent.*

W. W. HORTON, M.D.

RUTHIN CASTLE, NORTH WALES

REDUCTION OF FEES

In view of the present economic position, the inclusive fees at Ruthin Castle, formerly from 17 guineas a week, have been reduced to from 15 guineas a week.

The fees include medical attendance, all scientific investigations that may be needed, such as analyses, bacteriological cultures, the ordinary x-ray examinations, and electrocardiograph readings, all treatment that may be prescribed, such as special diets, insulin, artificial sunlight, electrical treatment, baths, massage, nursing, medicines or vaccines, board and lodging.

The only extra charge is that for a complete alimentary x-ray examination, or for x-ray therapy.

Many people who would go abroad for health will not do so this winter. All the usual forms of treatment are given at Ruthin Castle. The climate is mild. The annual rainfall is 30·5 inches, that is, less than the average for England. There is central heating throughout. Should the accommodation in the Castle not prove sufficient, comfortable rooms can be obtained near by for those undergoing treatment.

Address—THE SECRETARY, Ruthin Castle, North Wales. *Telegrams*: CASTLE, RUTHIN. *Telephone*: RUTHIN 66

BETHLEM ROYAL HOSPITAL, for Nervous and Mental Disorders,

Treasurer: SIR LIONEL FAUDEL-PHILLIPS, Bart.
Physician-Supt.: J. G. PORTER-PHILLIPS, M.D., F.R.C.P.

This Registered Hospital is now situated at Monks Orchard, in some 250 acres of park, pleasure, and farm grounds.
Applications can be considered on behalf of patients of the educated classes in a presumably curable condition.
With a view to early treatment voluntary or uncertified patients are admitted.
Patients who can contribute 5 guineas weekly towards the cost of treatment and maintenance may be received as vacancies arise. The Committee will also consider applications for admission at lower rates, and in certain cases will be prepared to admit patients free of charge.
Every facility for specialized investigation and treatment is provided in the Lord Wakefield Science and Treatment Unit. In this Unit is found the X-ray and Dental Departments and the Bio-Chemical, Pathological, and Psychological Laboratories.
Furthermore, provision is made for Electro-Therapy and Hydro-Therapy to be carried out in all their forms.
In addition to the Resident Medical Staff, Consultants in special branches of Medicine and Surgery are available whenever required.
The comfort of sensitive patients is greatly enhanced by the fact that the majority are given single bedrooms.
For forms and further particulars apply to the Physician Superintendent at the Hospital.

CAMBERWELL HOUSE, 33, Peckham Road, London, S.E.5.

INDIAN MEDICAL SERVICE

Recruitment of European Officers.

Applications are invited from medical men for permanent commissions in H.M.'s Indian Medical Service. The terms offered include a gratuity of £1,000 on retirement after six years' service, or £2,500 after 12 years' service, together with free return passages for those who no longer desire to remain in the Service. In other respects the terms will be as detailed below.

Candidates must be British subjects under 32 years of age at the time of application, and must be registered under the Medical Acts in force in Great Britain and Northern Ireland

CAREERS

The Indian Medical Service offers wide opportunities of medical experience, including clinical, preventive, specialist, and research work. At the beginning of his career an officer is employed on the military side, which has medical charge of the Indian Army. Promotion is on a time scale up to the rank of Lieutenant Colonel, and by selection to the ranks of Colonel and Major General. An officer may apply after one year's Indian service to have his name registered for transfer to the civil side, from which appointments are made to Civil Surgeoncies, which are established at the principal civil centres to provide for the medical needs of civil officials and for general medical administrative purposes, to specialist (for example public health and bacteriological) services, to research posts, and to professorships at the Medical Schools.

NOTE.—It is not possible to state at present what, if any, prospects of employment on the civil side will be open to Indian Medical Service Officers under the proposed new constitution for India.

PAY

Owing to the state of financial emergency at present prevailing in India the existing monthly rates of pay which are as follows are being subjected under the authority of the Secretary of State in Council, to a temporary reduction not exceeding 10 per cent.

Rank	Service in Rank	Full Pay	Overseas Pay	Years of Total Service
1	2	£	£	
Lieut.	—	456	1st 1st 2nd	1st and 2nd
Capt.	i. During first 7 years service as Captain	600	1st 1st 1st £15 £1	3rd 4th 5th 6th
	ii. With more than 7 and less than 6 yrs. service as Captain	720	£20 £25	7th 8th
	iii. With more than 6 years service as Captain	840	£30 £40	9th 10th and 11th
Major	i. During first 3 years service as Major	960		
	ii. With more than 7 and less than 9 years service as Major	1140		
	iii. With more than 9 years service as Major	1200		
Lieut.-Col.	i. Until completion of 23 years total service	1440	£50	12th and over
	ii. During 24th and 25th years service	1560		
	iii. After completion of 25 years total service	1680		
	iv. When elected for increased pay	1800		

EXTRAS.—In addition to the above rates various allowances are admissible for a large number of special appointments both the military and the civil side which may be held by members of the Indian Medical Service. Special high rates of pay are also attached to the number of administrative appointments open to officers in both branches of the Service.

ANTEDATES IN COMMISSION

Any service rendered by an officer during the war as a medical or combatant officer, or in a position usually filled by an officer may be counted as service for increments of pay, promotion retirement and retired pay, but not for gratuity.

One half of any service in the ranks during the war may be counted as service for retirement and retired pay only.

Candidates possessing certain higher medical qualifications may be granted an antedate of one year in their commissions. Past service in certain hospital appointments may also render candidates eligible for an antedate of one year. Persons holding or about to hold resident posts at recognized hospitals may be accorded in those posts for a period not exceeding one year. The maximum period of antedate, secondment or antedate and secondment combined, admissible under this paragraph, is limited to one year.

OUTFIT ALLOWANCE

Officers on appointment will receive an allowance of £50 towards the cost of outfit.

PRIVATE PRACTICE

With the exception of Administrative Officers, military or civil, and officers holding certain special appointments, officers are not debarred from taking private practice, so long as it does not interfere with their proper duties.

LEAVE

Leave can be taken at reasonable intervals, and adequate rates of leave pay are provided. Extra leave (known as study leave), which may not exceed 12 months in all during an officer's service, may be granted to officers desirous of pursuing special course of study of a post-graduate nature. During such leave, study allowance, at present fixed at the rate of £2 a day in the United Kingdom, £1 a day on the Continent of Europe, and £1 10 a day in the United States of America, is granted to an officer in addition to ordinary rate of leave pay.

PENSIONS

The rates of pension are as follows:

	Per annum £
After 17 years' service for pension	400
„ 18 „ „ „	440
„ 19 „ „ „	480
„ 20 „ „ „	500
„ 21 „ „ „	540
„ 22 „ „ „	580
„ 23 „ „ „	620
„ 24 „ „ „	660
„ 25 „ „ „	700
„ 26 „ „ „	750
„ 27 „ „ „	800

These rates are subject to alteration on account of a rise or fall in the cost of living as compared with the year 1919 to an extent not exceeding 20 per cent. in all. With effect from October 1st 1931, a reduction of 8½ per cent. has been made on this account from the amounts shown.

There are additional pensions ranging from £65 to £350 per annum for officers who have held administrative appointments.

PASSAGES

An officer on appointment is provided with free passage to India. The wives and families of officers who are married prior to the date of the officers' embarkation on first appointment will also be provided with free passage to India, subject to the payment of messing charges.

Officers and their families are also eligible for passage concessions under which they are granted a certain number of return passages home at Government expense during their service.

INSTRUCTION PRIOR TO EMBARKATION

Officers are required to undergo courses of instruction at the Royal Army Medical College and at other centres, lasting approximately six months, prior to the embarkation for India on first appointment.

Full details regarding these appointments and forms of application may be obtained from the Under-Secretary of State for India, Military Department, India Office, London, S.W.1. The Selection Committee will meet at the India Office early in January next, and the selected candidates will be required to join a course of instruction commencing early in February, 1932, prior to sailing for India in the Autumn of 1932. Applications should be submitted as soon as possible.

All Saints' Hospital (for Genito-Urinary Diseases).

In-patient Dept: 91, Finchley Road, N.W.8.
Out-patient Dept & Secretary's Office: 49/55, Vauxhall Bridge Road, S.W.1.

The Committee of Management invite applications for the office of HONORARY ASSISTANT SURGEON.

Candidates must be Fellows of the Royal College of Surgeons of England, or Masters in Surgery of a University in the United Kingdom.

Applications, accompanied by copies of testimonials, will be received by the undersigned on or before January 4th, 1932.

By Order of the Committee,
BEECHEY ROGERS, Secretary.

Sudan Government.

WELLCOME TROPICAL RESEARCH LABORATORIES, KHARTOUM.

Applications are invited for the post of BACTERIOLOGIST at an initial rate of pay £E.660 or £E.720 per annum (according to age and qualifications), with five or six biennial increases to £E.1,080, and thence after three years to £E.1,200. These rates of pay as well as the conditions of service are subject to Government rules and regulations from time to time in force. (£E.1 = £1 0s. 6d.)

Applicants must be unmarried, and will be expected to take up their duties immediately.

Applications, stating age, degrees, experience (with special reference to Pathology), and copies of testimonials, should be sent to the Director, Wellcome Tropical Research Laboratories, Khartoum, Sudan.

Further particulars regarding this post may be obtained on application to the Controller, Sudan Government, London Office, Wellington House, Buckingham Gate, London, S.W.1.

Liverpool County Borough.

LOCAL EDUCATION AUTHORITY.

JUNIOR ASSISTANT SCHOOL MEDICAL OFFICER.

Applications are invited for a Junior Assistant School Medical Officer, at a salary of £500 per annum, rising by annual increments of £25 to £700 per annum.

Applicants must be registered Medical Practitioners, and must have had at least three years' experience. It is desirable that they should have had some special experience in Diseases of Children.

The officer appointed will be required to devote whole-time service to the Education Authority under the direction of the Medical Officer to the Education Authority, and will be required to contribute to the Local Government and Other Officers Superannuation Act, 1922 (Substituted Scheme) as required by the Standing Orders of the City Council. Private practice will not be allowed.

Form of application, which may be had by forwarding a stamped addressed foolscap envelope, should be returned, together with copies of three recent testimonials, to the undersigned not later than December 9th, and endorsed "Junior Assistant School Medical Officer."

The canvassing of members of the Education Committee or the City Council is strictly prohibited, and will be considered a disqualification.

WALTER MOON,
Town Clerk, and Clerk to the Local Education Authority.

Salary £350 per annum, rising by annual increments of £25 to £450, with residential emoluments valued at £200 per annum.

The salary and value of emoluments are subject to deductions under the Local Government Officers Superannuation Act, 1922.

Further information relating to the appointment may be obtained from the Medical Superintendent, Southend Municipal Hospital, Rochford, Essex, to whom applications, with full particulars and copies of three recent testimonials, should be sent not later than Saturday, December 5th.

Town Clerk's Office, Southend-on-Sea.
November 21st, 1931.

H. J. WORWOOD, Town Clerk.

London County Council.

The LONDON COUNTY COUNCIL invites applications from Surgeons, duly qualified by experience in Diseases of the Ear, Nose and Throat, for appointment as CONSULTING LARYNGOLOGIST in its Sanatoria and Hospitals for Pulmonary Tuberculosis. The remuneration is at rate of 200 guineas a year to cover visits once a month to each of the four Hospitals, and once every two months to each of two Hospitals. Three of the Institutions are on the outskirts of London, and the other three are near Godalming, Wokingham, and Brentwood, respectively. To suit the convenience of applicants, the Council may divide the work between two Laryngologists and revise the remuneration. Appointment will be for twelve months in the first instance, and rate of remuneration and conditions of service will be subject to review by the Council.

Forms of application obtainable (stamped addressed foolscap envelope necessary) from Medical Officer of Health (Staff Division 4a), County Hall, Westminster Bridge, S.E.1, returnable by December 18th.

Canvassing disqualifies.

London County Council.

The LONDON COUNTY COUNCIL invites applications for appointment as HOUSE PHYSICIAN at LEWISHAM HOSPITAL, High Street, Lewisham, S.E. Salary £80 a year, together with board, lodging, and washing. Appointment is for six months only in the first instance. Candidates must be qualified Medical Practitioners, but need not necessarily have had previous Hospital experience. Person appointed will be required to live in the Hospital, to carry out such duties as may be assigned by Medical Superintendent and, should occasion arise, to assist at any of the other establishments under the control of the Council.

Forms of application obtainable (stamped addressed foolscap envelope necessary) from Medical Officer of Health (Staff Division 4a), County Hall, Westminster Bridge, S.E.1, returnable by December 18th. Canvassing disqualifies.

Further inquiries should be addressed to Medical Superintendent at the Hospital.

London County Council.

Applications are invited for appointment to the undermentioned positions. Persons appointed will be required to carry out such duties as may be assigned by the Medical Superintendent and, should occasion arise, to assist at any of the other establishments under the control of the Council. Successful candidates will be required to live in the Hospital.

NORTH-EASTERN (FEVER) HOSPITAL, St. Anne's Road, Tottenham, N.15.—ASSISTANT MEDICAL OFFICER. Salary £350 a year, rising annually by £25 to £425 a year, together with board, lodging, and washing. Candidates must be qualified Medical Practitioners of at least one year's standing, and it is desirable that they should have held a resident appointment in a General Hospital for at least six months. Person appointed will receive training in radiological work, with a view to acting as deputy to radiologist at the Hospital.

NORTH-WESTERN (FEVER) HOSPITAL, Lawn Road, Hampstead, N.W.3. — HOUSE PHYSICIAN (man only). Salary £80 a year, together with board, lodging, and washing. Appointment is for six months only in the first instance. Candidates must be qualified Medical Practitioners, but need not necessarily have had previous Hospital experience.

Forms of application obtainable (stamped addressed foolscap envelope necessary) from Medical Officer of Health (Staff Division 4a), County Hall, Westminster Bridge, S.E.1, and must be returned by December 30th. Canvassing disqualifies. Further inquiries should be addressed to Medical Superintendent at the Hospital.

City of Sheffield.

Advertising Helps the Reader

Readers of the Journal are presented week by week with a comprehensive summary of products necessary to the medical man both in his professional and private life. The advertisement pages of the Journal are carefully scrutinised before going to press, in order that our readers may deal confidently with those firms whose announcements win their interest and attention.

Modern advertising seeks to increase demand, thereby stimulating production and building a circle of prosperity, which ultimately reacts to the advantage of the purchaser himself. Advertised products necessarily maintain a high standard of excellence, for disaster must naturally come speedily to the manufacturer who through any cause and at any time loses the confidence of his customers.

It is the policy of the Journal to convince advertisers that doctors prefer to be approached directly through the pages of their own publication, for in this way we believe manufacturers are encouraged to consider the special needs of the profession, and to state clearly the results of their efforts to meet these requirements when seeking orders from medical men.

The "small" advertisements section provides a *forum* for the "domestic" business of the profession, and those wishing to arrange the Sale or Purchase of Practices, requiring Assistants or Assistancies, and Partners or Partnerships, may in these pages reach thousands of their fellow medical men at very economical cost. Such transactions may, in addition, be protected by the secrecy which the free Box Number service provides.

"MEDICAL PARTNERSHIPS, TRANSFERS, AND ASSISTANTSHIPS" (BARNARD & STOCKER) Post free 12 6

All communications to be addressed to Mr. A. V. STOREY, General Manager.

WHETHER THE PATIENT IS

aged  and feeble  or so young  that his digestive system works less energetically than his limbs  or is an adult business man  healthy but deskbound  — prescribe AGAROL with confidence for the relief of constipation and to aid in restoring regular bowel function.

AGAROL Brand Compound is the original mineral oil and agar-agar emulsion with phenolphthalein. It softens the intestinal contents and gently stimulates peristalsis.

Gentle enough for little patients; active enough for the chronic state of the adult and aged patient.

A supply gladly sent for trial.

AGAROL *for Constipation*

BRAND COMPOUND

FRANCIS NEWBERY & SONS, LTD., 31-33, Banner Street, London, E.C.1.

Prepared by WILLIAM R. WARNER & CO., INC., *Manufacturing Pharmacists since 1856.*

Printed and published by the British Medical Association, at their Office, Tavistock Square, in the Parish of St Pancras, in the County of London

SCIENTIFIC ENZYME DIGESTION

RICH SELECTED ENGLISH MILK
Pancreatised

PREDIGESTED MILK
(25% Protein Conversion)

SELECTED ENGLISH WHEAT
Dextrinised and Pancreatised

PREDIGESTED WHEAT
(25% Starch Conversion)

Powdered by the
COW & GATE
Improved
Roller Process

Peptalac
REGD.

THE NEW INSTANT PREDIGESTED FOOD

SIX OUTSTANDING ADVANTAGES

1 PEPTALAC is "made in a minute" by the simple addition of hot water giving in an instant a digested milk food of high digestibility.

2 PEPTALAC is fool-proof and requires neither technique, skill nor addition of milk. It renders obsolete the method of peptonisation wherein milk had to be held at a temperature 117°F. for 20-30 minutes under carefully controlled conditions.

3 PEPTALAC is guaranteed to have been pancreatised and the essential components of starch and milk proteins broken down to sugars, peptones, and amino-acids. With other methods of peptonisation this cleavage is uncertain and unreliable and the milk which is added is not predigested.

4 PEPTALAC is a safe and practically sterile powder. In the old methods of peptonisation, the milk was predigested at a temperature which is also favourable to the growth of organisms, thus resulting in a final product teeming with bacteria. Reconstituted PEPTALAC is free from pathogenic organisms and practically sterile.

5 PEPTALAC is therefore invaluable for infants, young children, the aged, convalescents, and the weak in health, who are prone to contract milk-borne diseases from ordinary milk or preparations made with it.

6 PEPTALAC is pleasing to the most fastidious palates—salt or chocolate may be added for further flavouring if desired.

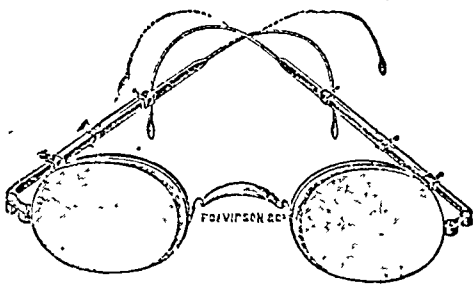
110 HONOURS & AWARDS



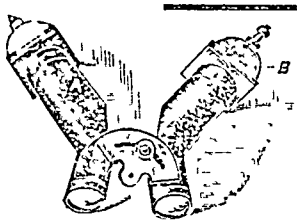
SOMETHING NEW AND INVALUABLE TO EVERY PRACTITIONER

THE "DAVON" (Reg.) FUNDUSCOPE

BRITISH

A perfect and inexpensive little instrument for obtaining a rapid view of the fundus with remarkable field and definition.

Price £2 0 0;
or with red free condenser in addition £2 5 0.
Send for descriptive leaflet.



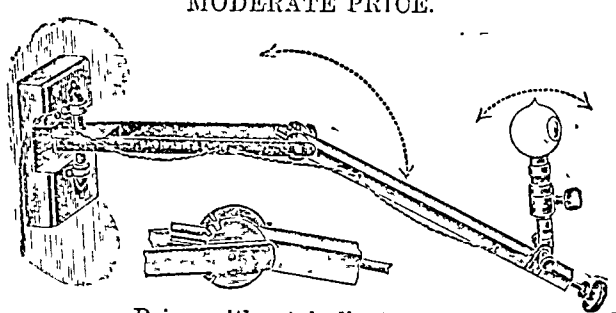
BISHOP HARMAN "STEREO" LOUPE, comprising 2 Spheio-prisms with the bases together, mounted in a solid nickel spectacle frame, with curl sides which are adjustable for length.

It is worn low down on the nose so that one can look over it as well as through it.

"Wonderfully comfortable in use—the best thing of its kind" ——, M.D.

Complete in Case ... £1 10 0

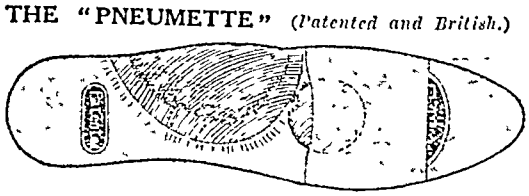
No 529B.



"WORTH" AMBLYOSCOPE

for patient's own use with 6 pictures.

£1 17 6.



THE "DAVON" BRACKET.

Well made and serviceable at a very MODERATE PRICE.

Price without bulb £2 2 0.
Target frosted bulbs (please state voltage) each 3/6.

THE "PNEUMETTE" *(Patented and British.)*

THE ONLY FOOT ARCH SUPPORT WITH AN AIR CUSHION. PAMPHLET ON FOOT TROUBLES, with an Article, "The Medical Aspects of Flat Foot," by an eminent London Physician, free

"I have prescribed 'Pneumettes' for several of my patients with remarkably good results in every case." ——, M.D.

"DAVON" TRANSFORMERS

FOR LIGHT & CAUTERY

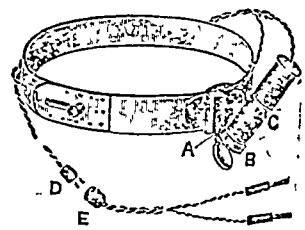
FROM ALTERNATING MAINS (please state voltage)

Made on a new principle.

EARTH FREE.

Minimum Current Consumption.

No. 83. £6 10s. (weight 14 lbs.)

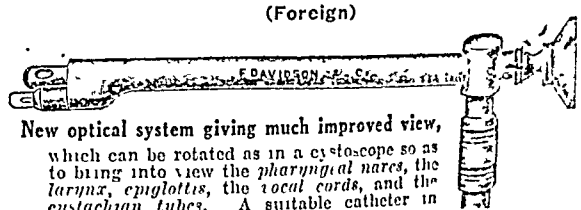


Descriptive leaflet free.

No. 82. For Light Only (0 to 8 volts) £1 18 6. (weight 3½ lbs.)

Perfect appliances, impossible to get out of order.

THE "DENIS BROWNE" HEAD LAMP.



No. 516. £2 17 6.

"This gives a more brilliant and concentrated beam than any other on the market. At the ordinary working distance of 15 inches it gives a perfectly clear, evenly illuminated field of 4 inches in diameter which changes very little at longer or shorter working ranges. Its only adjustment is single strong hinged joints, which gives all the directions of the light which are needed, and, in addition, it does not project forward from the operator's face"

DENIS BROWNE, F.R.C.S.

LARYNGO-PHARYNGOSCOPE

(Foreign)

New optical system giving much improved view, which can be rotated as in a cystoscope so as to bring into view the *pharyngeal nares*, the *larynx*, *epiglottis*, the *vocal cords*, and the *eustachian tubes*. A suitable catheter in position is easily observed.

With Handle and Cords £5 15s. In Walnut Box £6 5 0

"Davon" Dry Battery for above 0 7 6

With "Davon" Battery, and Rheostat in Walnut Box 7 5 6

With battery in handle (not the "Davon") £5 15s. In Walnut Box 6 5 0

Or complete with Electric Auriscope for diagnosis, operating, aspirating, and massage, in Oak Case 8 15 0

1932 Catalogue free.

FELAMINE BRAND SANDOZ

SANDOZ

An association of the most powerful cholagogue—pure crystallised cholic acid—and the classical biliary disinfectant—hexamine, entirely free from accessory substances.

Indications:

CHOLANGITIS, CHOLECYSTITIS, HEPATIC INSUFFICIENCY, HEPATIC CONGESTION, JAUNDICE, CHRONIC CONSTIPATION.

Felamine is supplied in Bottles of 50 and 250 Tablets.

AGENCY:-

SANDOZ CHEMICAL WORKS PHARMACEUTICAL DEPT.

5, WIGMORE STREET, LONDON. W. 1.

VARICOSE VEINS

Complications Arising from the Injection Treatment

The excessive inflammatory reactions following this method of treatment may be the result of a too-rapid initial injection with a highly concentrated solution, or to diffusion of a small amount of the solution, through the vein wall.

In these cases there is a diffused redness, swelling and inflammation, accompanied by pain and tenderness resembling cellulitis.

Antiphlogistine Brand Dressing applied over all the venous segment will quickly relieve these painful phenomena. Its use is advocated by Tournay and Fabre, collaborators of Sicard and leading exponents of his method.

OXFORD MEDICAL PUBLICATIONS

THE FUNDUS OF THE HUMAN EYE

An Illustrated Atlas for the Physician

By ERNEST CLARKE, C.V.O., M.D., F.R.C.S.,

Consulting Surgeon to the Central London Ophthalmic Hospital, etc.; Hon. Fellow, Downing College, Cambridge

The advent of the luminous ophthalmoscope has now brought ophthalmoscopy within the reach of all, and this instrument is becoming as much a part of the physician's equipment as the stethoscope. But although now it is easy to see the fundus of the eye, it is not so easy to interpret what is seen, and the observer wants a small, handy atlas that he can easily consult. It is hoped that this little book will supply this need. Each plate is printed in natural colours on thin card, bound separately on a linen hinge into the cover, thus allowing the book to open flat at any page. Beneath each plate appears a short description of the condition it illustrates. The fundus is enlarged to a uniform diameter of nearly four inches throughout. Only the commonest fundus changes have been illustrated, and the description of the plates has purposely been made as brief as possible.

51 Colour Plates. Size of Atlas 8¾in. × 5½in. 18s. net.

INJURIES AND SPORT

A General Guide for the Practitioner

By C. B. HEALD, C.B.E., M.A., M.D.(Cantab.), M.R.C.P.(Lond.),

Physician in Charge of Electrotherapeutic Department, Royal Free Hospital, Physician to the British Red Cross Clinic for Rheumatism; Consulting Physician in Electrotherapy, Royal Air Force

Contents include —Repair as a Repetition of Development—Development and Repair in the Various Tissues—Diagnosis of Injury—Immediate Care of Injured Patient—Principles of Splinting and Support—Electrotherapeutics—Physiotherapeutics—Factors Modifying Recovery from Injury—Complications following Injury—Injuries to the Shoulder Girdle—To the Arm and Elbow—To the Forearm and Hand—To the Lower Back and Pelvis—To the Hip, Thigh, and Knee—To the Leg and Foot—To the Head, Neck, and Thorax—Re-educational Therapy—Blood Transfusion Service, etc.

Pp. 567. 380 Illustrations. 25s. net.

A New (Second) Edition of

POCKET ATLAS OF ANATOMY

By VICTOR PAUCHET and S. DUPRET

The many original features of this work can only be appreciated on actual inspection. It consists of a series of plates, many of them printed in colour, depicting all regions of the human body, also individual organs, systems, and structures. No text is included, except the necessary marginal keys which appear on each plate. The old terminology is used throughout, but B.N.A. equivalents are given in the table. An alphabetical list of plates, and a full anatomical index, is included. In this edition, twenty-eight new plates have been added, and all alterations and corrections made to others where necessary.

Pp. 390. 345 Plates, 173 in Colour. Size 7¼in. × 4½in. 12s. 6d. net.

A New (Fourth) Edition of

DISEASES OF THE GUMS AND ORAL MUCOUS MEMBRANE

By Sir KENNETH GOADBY, K.B.E., M.R.C.S., L.R.C.P., D.P.H.(Cantab.),

Lecturer on Bacteriology of the Mouth, Dental Department, University College Hospital, Specialist Medical Referee for Industrial Diseases, London and Home Counties (Home Office), Late Bacteriological Specialist, Royal Herbert Hospital, Woolwich; Erasmus Wilson Lecturer, Royal College of Surgeons, 1907, Hunterian Professor, Royal College of Surgeons, 1911.

Contents include —Gingivitis—Dental Caries or Decay of the Teeth—Diseases of the Dento-Alveolar Articulation (Tooth Sockets)—Diseases Originating from Mouth Affections—The Bacteria of the Human Mouth—Ulceration of the Gums—Tumours of the Gums and Investing Tissues—Diseases of the Mouth and Gums—Diseases with Oral Symptoms—Neuralgia and Mouth Neuroses—Principles and Methods of Diagnosis in Oral Disease—Vaccine Therapy.

CO_2 IN RESUSCITATION.

"F.B.R.," in the "British Medical Journal," Nov. 7, 1931, page 878, writes:—

"Apropos CO_2 as a respiratory stimulant, at a recent confinement, as the result of premedication of the mother, of instrumental delivery, or of some cause unknown, the child was born in a condition of partial asphyxia. Half an hour's effort to restore respiration proved ineffective, beyond producing a spasmodic inspiratory gasp at intervals. The baby appeared to have definitely decided not to remain. It then occurred to me to try the "Sparklet" apparatus, or, I should rather say, contrivance, which one carries in the anaesthetic bag. The result of discharging a little CO_2 in front of the baby's mouth at the moment of its making a rare inspiratory effort was instant and amazingly effective. The rhythm was started, and in a few minutes all anxiety had vanished. Admittedly there is nothing startlingly new in this phenomenon. I feel, however, that I am justified in relating the experience from the conviction that the average practitioner is unaware that he has to his hand a simple inexpensive little CO_2 container, suggested by a Manchester anaesthetist and manufactured by the "Sparklet" people. I now feel it should have a place in every midwifery bag, and that it will save many an infant life."

The Vicar's Christmas Hint

"Everybody who knows me," remarked the Vicar, "knows that I smoke Three Nuns. But possibly some may be unaware that there's a special half-pound tin of this grand old blend to be seen in the shops just now. It has a useful screw-on lid that keeps the tobacco in perfect condition, so if more than one good friend happened to hit upon the same idea for a Christmas gift, the recipient would welcome them all with open arms . . . Need I say more?"

LODGE PLUGS LTD.—RUGBY

SURGICAL BELTS ALONE DEAL WITH THE ROOT CAUSES OF INTERNAL DISPLACEMENTS

The mechanical engineering of the abdomen in cases of internal displacement is now the first concern of patient and physician. X-ray photographs reveal irrefutably that aperients and intestinal antiseptics are futile in such cases. The long and frequently disappointing records of surgical intervention of a formidable and dangerous kind, show clearly how little this form of treatment achieves. The medical profession is beginning to realise that the surgical belt—giving upward support—can alone deal successfully with the root cause of mankind's tendency to sag—the downward pull of gravitation.

Domen Surgical Belts are constructed to give ample upward support from the only anatomically legitimate foundation—the pelvis. And they do this without harmful pressure—without embarrassment to the patient. Domen belts are designed for specific complaints and are strong, durable and light. Full information will be sent on receiving your card or a telephoned request.

DOMEN SURGICAL BELTS

DOMEN BELT CO. LTD., 26, SLOANE STREET, LONDON, S.W.1. Telephone: Sloane 2524

Belts by Roussel combine Hygienic Figure Control with Beauty of Form

Patented in U.K.

LONG-BELT.

Prices: In strong thread elastic, £4 4s.; in firm and supple thread and silk elastic, £5 15s.; in extra fine and supple elastic, all pure silk, £9 9s. Hip belts 13" deep and upwards from 30s. Post free in U.K.

Designed on strictly anatomical lines by the famous Paris corsetier, Roussel Belts combine the advantage of a medical appliance with the assurance of a beautiful figure.

Doctors are agreed that recent fashions, demanding little bodily support, have been the cause of troubles such as obesity, sagging abdominal muscles, enteroptosis and gastroptosis. Some support is needed, and many of the Medical Profession now recommend the Roussel Belt. It is a definite step forward in modern Belt construction and is to be advised particularly for post-operation and maternity wear.

Woven to individual measurements, in a special light porous elastic which maintains a continuous massaging action while in wear, Roussel Belts are ideal for women who wish to have healthy and beautiful bodies.

Because complete satisfaction is dependent upon perfect fitting, Belts by Roussel are sold only through Roussel Salons as listed below.

SURGICAL SERVICE
SALTAIR

"SALTAIR SURGICAL SERVICE"

Efficiency-

in Surgical Appliances

To attain the high state of Efficiency that ALL Salt's Surgical Appliances possess, the following points are rigidly adhered to:—

- They must FIT .... accurately.
- They must give EXACT degree of support .... otherwise they are useless.
- They must ensure CORRECT remedial treatment .... thus preventing relapse.
- They must give such COMFORT to the patient as to secure his (or her) co-operation with the treatment prescribed .... a most important point.

SURFACE THERAPY

THERMOGENE brand of Medicated Wadding is the ideal counter-irritant for routine use. It acts by stimulating the cutaneous nerves, sending reflex impulses to deeper areas where they bring about vascular changes.

Pain is eased, and congestion is relieved, by the flow of fresh blood, with consequent de-toxication and cleansing of the affected part.

Unlike poultices, pastes, ointments, and oily liniments, THERMOGENE brand of Medicated Wadding does not clog the pores of the skin or soil the linen.

THERMOGENE brand of Medicated Wadding is a carefully prepared pure cotton wadding, remarkably soft and fleecy, freed from dust and other impurities, and impregnated with skin-stimulating vegetable essences.

THERMOGENE

ANTI-TYPHOID-PARATYPHOID (T.A.B.) ORAL VACCINE

Administration of this protective vaccine by mouth is now an established alternative to the usual hypodermic method for immunisation against the enteric diseases, and has the advantage of avoiding all reaction.

This method is especially indicated where rapid immunisation is desired, as in the case of contacts; or when facilities for hypodermic injection are lacking.

Issued in packages containing three doses of killed emulsion, with three bile tablets for oral administration on three successive mornings. Full instructions accompany the package. Price 17/6 per set.

Prepared under Licence from the Ministry of Health in the

LABORATORIES OF PATHOLOGY AND PUBLIC HEALTH,

Telephone: LANGHAM 1434. 6, HARLEY STREET, LONDON, W.1.

CHRISTMAS AND NEW YEAR'S GIFTS

Special terms will be quoted to Medical Practitioners (only) for the supply of The Doctor's China Tea in post free parcels to any address. There is nothing so acceptable as fine China Tea.

THE DOCTOR'S CHINA TEA

FOR ALL CASES OF GASTRIC TROUBLE.

It is definitely not safe to allow any tea but China tea to be used when there is the slightest tendency to gastric trouble. The Doctor's China Tea has no excess of Tannin whatever—it is a really good blend of China tea—it is therefore ideal as a delicious and healthful drink for all who enjoy a good cup of tea and especially for those of your patients who suffer from any form of indigestion.

Priced at 3/- and 3/8 per lb. A super quality at 4/2 per lb.

MARMITE—A well-tried dietary corrective

For many years the Medical Profession has had ample clinical evidences of the beneficial effects of the addition of Marmite to the diet. An extract of Yeast, Marmite is probably the most palatable form in which adequate supplies of Vitamin B may be administered. Marmite has proved most helpful in combating fat intolerance, loss of weight, Marasmus and similar conditions. The patient will always welcome the introduction of Marmite because of its appetising flavour.

Medical Practitioners are invited to write for a sample of Marmite, together with full evidence of its usefulness. The Marmite Food Extract Co. Ltd., Walsingham House, Seething Lane, London, E.C.

TO COUNTER ACIDOSIS

As SALVITAE contains 59% of Potassii et Sodii Citro-Tartras and 30% of Sodii Sulphas it is of great value both in maintaining health and in the treatment of disease, through eliminating deleterious nitrogenous products and favourably influencing circulation, glandular secretions, peristalsis, and metabolism.

The fruit acids of SALVITAE are converted in the system into potentially basic alkaline carbonates, thus enabling the blood to keep the uric acid compounds in solution, and facilitate their removal.

A formula that demonstrates its scientific value.

Local Anæsthesia in Surgical Practice

REMOVAL OF GOITRE

Typical Case

C. C. H., male, aged 46 years.

Diagnosis: Toxic colloid goitre.

Operation: Partial lobectomy.

Anaesthesia: Local infiltration and cervical block. 120 c.c. of a 0.5 per cent. Novocain-Adrenaline solution were used.

Operation: Classical subdermal infiltration and cervical block was made. 60 c.c. of 0.5 per cent. Novocain-Adrenaline solution were introduced subdermally, and 30 c.c. were used on each side for blocking the cervical nerves. A large intrathoracic colloid goitre was removed from the left and a small adenoma from the right.

—EXTRACT from PRACTICAL LOCAL ANAESTHESIA (Farr).

(Full technique of this and one hundred other operations under Local Anaesthesia will be found in the above work, published by Henry Kimpton, 263, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANAESTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify "Novocain" for your next operation.

Does not contain Cocaine, and does not come under the Dangerous Drugs Act.

FULL LISTS ON APPLICATION

CALCIFEROL

(Crystalline Vitamin D)

Following the recent publication of an announcement that British scientists have succeeded in isolating Vitamin D in a crystalline form (*Nature*, 1931, Vol. 128, p. 758) The British Drug Houses have undertaken the manufacture of this pure crystalline Vitamin D (named Calciferol), and they now offer it for the use of research workers.

Calciferol is a white substance of definite crystalline structure, and of absolute purity; it possesses an unvarying Vitamin D activity of 40,000 units per mg.

Calciferol is issued in tubes of 0.1 gram which are obtainable from the makers at 12/- each.

The introduction of Calciferol makes yet another addition to the following list of B.D.H. Standardised Vitamin Products exhibiting Vitamin D:—

RADIOSTOL (Vitamin D)
RADIOSTOLEUM (Vitamins A and D)
RADIO-MALT (Vitamins A B_1 B_2 and D)

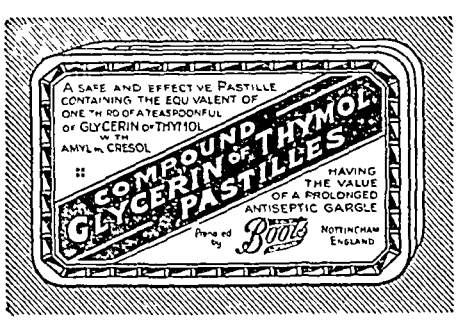
Symptomatic relief in 5 minutes

THE symptoms of common cold—congestion, discharge and obstructed breathing—are frequently distressing. From the patient's point of view, they constitute the essence of the annoyance from which he is seeking immediate relief.

Rapidity of action is characteristic of Mistol. Consisting of menthol, camphor, eucalyptol, and chlorbutol in a light oily solution that spreads promptly to all parts of the nasal mucosa, it relieves congestion, reduces discharge and clears the nasal passages within five minutes.



This symptomatic improvement also benefits the pathological state and tends to shorten the duration of the cold. Venous stasis in the mucous membrane is corrected, hyperemia diminished, and over-activity of the secreting glands checked. Repeated instillations of Mistol promote a more rapid return to normal conditions within the nares.

The formula of Mistol is the result of long and careful research, suggested primarily by prescriptions used for many years by leading rhinologists.

FAMILIARITY BREEDS CONTEMPT

Are we not, at times, inclined to allow practical activities to cloud our perception of the familiar fact, that Dental Caries is an almost *incurable* disease?

As every doctor knows, this is one of those pathological conditions that show little, if any, tendency towards spontaneous cure, or even arrest, of its ravages. The only scientific method of combating this affection is through preventive measures. And it is this truth that is the keynote of all Gibbs Advertising propaganda. Care of the teeth, cleanliness of the mouth, are urged as first principles.

In the great national and provincial newspapers; in the most widely read magazines, many millions of Gibbs messages are carried from end to end of the kingdom. And every message can be crystallised in that oft'-repeated phrase: "Visit your Dentist twice a year, and use Gibbs Dentifrice twice a day."

It is in such practical ways as these that Gibbs work hand in glove with Doctors and Dentists — never failing to depict them as the highest and final authorities on all matters connected with the teeth.

GIBBS DENTURE TABLET

Gibbs new Denture Tablet is for cleaning Dental Plates (both gold and vulcanite), Bridgework and artificial teeth. It gives a high polish, removes stains, makes plate or teeth sterile and antiseptic without in any way injuring the softest gold or the finest vulcanite or platinum. The product has been approved by important members of the Medical Profession.

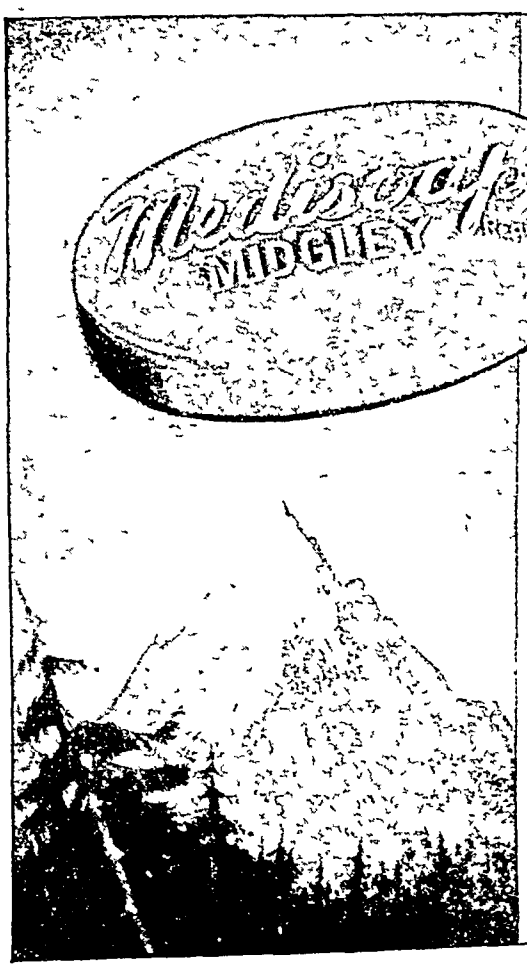
OVALTINE

IN GALACTOSIS

Diet in lactation is a matter of no less importance than diet during pregnancy.

"Ovaltine" completely meets the requirements of the diet of the nursing mother by providing adequate and appropriate nourishment It is easily digested, wholly nourishing, and does not convey any noxious or unpalatable substances to the breast milk. For these reasons "Ovaltine" will be found a most dependable prescription for establishing galactosis.



"Ovaltine" is recommended to be given about the sixth month of gestation and should be continued throughout the nursing period. A rich milk secretion is thus encouraged and the health of the patient safeguarded against overstrain.

As an example of the nutritive power of "Ovaltine" it may be stated that one cupful yields more nourishment than 3 eggs or twelve cups of beef-tea.

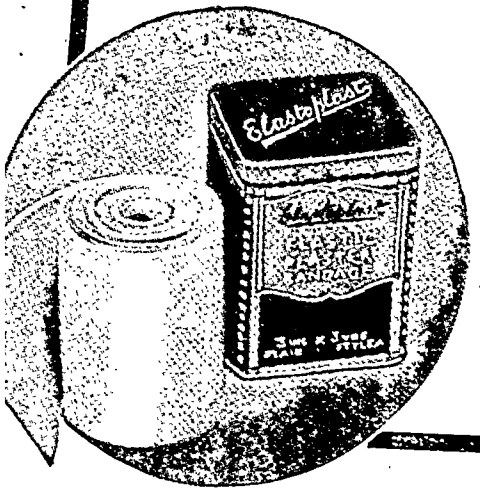
MODERN BANDAGING TECHNIQUE

In the case of any injury which involves muscles, joints or ligaments, bandaging with Elastoplast affords, *par excellence*, the last word in effective treatment. It should be firmly applied over the whole joint and for some distance above and below, and should be used as soon after the accident as possible, thereby minimising the amount of oedema. The patient is made more comfortable and convalescence is hastened.

ELASTOPLAST ELASTIC PLASTER is not only the proved cure for Varicose Ulcer, but is also acknowledged as ideal for all surgical and orthopaedic purposes.



ELASTOPLAST WOUND DRESSINGS combine medicated gauze and lint pads with the elastic plaster base. They provide speedy and efficient dressings for cuts, wounds, incisions, boils, etc.

VISCOPASTE BANDAGES (Unna Paste Type), a valuable adjunct to the after-treatment of Ulcer with Elastoplast.

SEMIPLAST. A new idea in Elastic Plaster. Ideal for Varicose Veins and all support as only the first turn of the plaster comes into contact with the skin.

CELLONA. The new improved P.O.P. bandage moistens in 5 seconds—sets in 5 minutes. 50% lighter—cleaner—easier to apply and handle than the usual P.O.P. bandage.

Insist on the original and finest elastic plaster, which stretches from 3 to nearly 6 yards.

Elastoplast

Patent No. 253.527.

Remarks on "FAILED FORCEPS"*

BY

J. ERIC STACEY, M.D.Lond., F.R.C.S.Ed.

HON. CLINICAL ASSISTANT SURGEON, JESSOP HOSPITAL FOR WOMEN, SHEFFIELD

In choosing a subject from my special branch of medicine I am guided by certain considerations, one of which is that while we are a body of workers engaged in every branch of medicine, the main bulk of the members of this society are in family practice, in which midwifery looms large as the bane and worry of existence. In addition, there is not one of us but is constantly being confronted with the results of some sequel to a confinement which bears fruit in ill-health and impaired functions of the mind and body. It is a reflection on our progress that the maternal mortality and morbidity rate is but a trifle better now than it was in the days immediately succeeding the introduction of Lister's epoch-making practices. In fact, the Registrar-General's returns for 1929 show a slightly higher rate than any other of the last decade, except that of 1921. This, of course, may in part be accounted for by a better system of notification, and by a better and more scientific description of the cause of the mortality or morbidity in cases which were previously labelled with an inadequate or faulty diagnosis; but, despite any excuses which we may put forward, the distressing fact remains that the risks attendant on child-bearing have not materially diminished by any contribution of medical science during all these years. There is, however, one way in which this doleful picture may be somewhat brightened—namely, by eliminating the cases of failed forceps.

Definition

I have been asked one or twice exactly what is meant by the term "failed forceps," and I can only say that it is self-defining if we add the words "in midwifery," but I propose to confine my address to an analysis of a series of cases in which an ineffective attempt at delivery had been made with forceps and successfully accomplished later by a similar operation or other manœuvre.

We should, I suppose, include under the heading of "failed forceps" all those cases in which we anticipate that delivery will be effected by the use of forceps and in which we have to remove them for any purpose, possibly to confirm our diagnosis of the presentation, and then proceed on a reapplication to bring about the result we have aimed at from the first. In the majority of such cases we should reflect carefully whether we were wrong in the first place to adopt this method of delivery, or whether our technique was untutored. I propose, however, to omit all these cases, not because they would include a large number in which I have figured as obstetrician, but because my records would be difficult, even impossible, to obtain with any accuracy, and because the term "failed forceps" is one which is now in common usage for cases which I have defined as included in the subject-matter of this paper.

Commissions have been sitting, scientific discussions have taken place, and the public imagination has been roused by the inefficient midwifery service provided in this, and I may say, in all other countries, and to us as medical men little has been brought out more strikingly than the sepsis which follows in the train of forceps application or other obstetric operation. For this, the result of an inadequate service, the general public is largely to blame. Once a student has attained to the dignity of qualification he is expected to deal with all and every complication of midwifery, many of the cases involving as much skill in diagnosis as the most complicated medical case, or the dexterity in manipulation of a major surgical operation skilfully performed. Of the various obstetrical manœuvres employed none perhaps requires greater knowledge than the application of forceps, if a successful result to both mother and child is to be attained—a knowledge not only of how, but also when, to resort to their use, demanding in all cases a diagnostic capacity and technical dexterity which it is not right and proper to expect from a student taking out his obstetrical practice. One remedy lies in better teaching facilities, both for the undergraduate and for the man in practice.

In 1928 Dr. Douglas Miller of Edinburgh published a series of cases, and in my analysis I have followed very much the lines he adopted in his. The 154 cases reviewed are a consecutive series which occurred in the practice of the Jessop Hospital for Women during the years 1924–28. I have taken no later case because of the review of the remote after-results.

Etiology and Associated Conditions

Reviewing now the 154 cases from the etiological point of view, many interesting but certain unhappy facts are brought to light.

Early Rupture of Membranes

In 115 cases the membranes ruptured early, and in 88—that is, 77 per cent. (or 57 per cent. of the total), they had been ruptured artificially before the cervix was sufficiently dilated to admit of the passage of a head with a diameter of 3¾ to 4 inches. In the majority of cases this is a regrettable accident or error, and care should be taken to obviate its occurrence.

Many of the cases under review were midwives' cases, in which the doctor was called in after this expedient for accelerating labour had failed, or, in many cases, had had an opposite effect. I am convinced that in a large number of cases of primary uterine inertia and of secondary uterine inertia leading to lingering labour the source of the trouble lies in this practice. It is easy to see how often this potent source of trouble arises. In a large number of cases, particularly in multigravidae, when the patient reaches the second stage of labour with unruptured membranes, they immediately give way spontaneously, or are ruptured artificially; the patient has a few expulsive contractions and the infant is born. If the first time the attendant on the labour sees the patient is when she is in the second stage, and a happy result is brought about rapidly by rupturing the membranes, then it is easy to understand how a series of successful issues may so cloud the judgement that the expedient is tried without due regard to the stage of labour. In many cases where this is done no ill result occurs, even when the patient is only in the first stage, and the faulty manœuvre is employed over and over again, until a case arises where, to the chagrin of the attendant (in 70 per cent. of the cases this is not a doctor) the condition is aggravated.

Most of us have had under our care those trying cases of lingering labour, due to primary uterine inertia, in which no etiological factor is evident beyond this early rupture of the membranes, which may even have happened before labour started—cases in which labour trails on for hours, or even days, with all the accompanying risks to mother and child. Too often are we tempted to hurry on the labour by ill-timed application of forceps. I, personally, am more concerned as to what shall be the *modus operandi* when confronted with this problem than with almost any other difficulty in obstetrics.

* Lecture given before the Sheffield Medico-Chirurgical Society.

INCOMPLETE DILATATION OF CERVIX

In exactly 100 cases (66 per cent.) of the 154 cases reviewed the patient had, when the forceps were applied, a cervix which was not adequately dilated to deliver the child. As almost all the cases were at full term, it was extremely unlikely that, even if delivery were effected, it would be accomplished without some damage to the mother, which would be evidenced at the time or later.

The term "full dilatation" needs no explanation, but, when it is realized that in a large number of cases the child's head was badly flexed, then in these cases particularly it was more important for full dilatation to occur, as the normal *engaging diameter of the child's head* (S.O.B. of 3¾ inches) was often thereby converted into an abnormal one (S.O.F. 4 inches, or even an O.F. of 4½ inches). This non-dilatation of the cervix was not the sole obstructing cause of failure of delivery in the 100 cases I mention, but was in many instances combined with a faulty presentation, such as occipito-posterior or a contraction of the pelvis, or even all three combined.

However, a further analysis of the cases established that in 47—that is, practically one-third of all those investigated—no other cause accounted for the failure in delivery than an incompletely dilated cervix. The degree of insufficient dilatation varies enormously, from that in which it would almost seem to be impossible to pass the blades of the forceps through the os, up to slight degrees of non-dilatation—for example, where the os has a diameter of less than 4 inches.

While on the question of the undilated cervix may I utter a warning about one of the unpleasant consequences which may ensue from ill-advised efforts to stretch the cervix. We all remember that property of the uterus known as its polarity. By traction on the child's head through an undilated cervix this contraction of the uterus so set up may not be regular and rhythmic as we wish, but may be irregular, and bring about the formation of what is called an internal contraction ring, which is really a localized toxic uterine spasm, often in the form of a circular constriction. This is not to be confounded with a Bandl's ring, and cannot be recognized except by internal examination. Should this occur, then the worst possible thing is for further attempts to be made at delivery, aggravating the already too irritable organ.

I have often been asked whether a cervix which has at one time been dilated can again close down, so that when a second examination is made later there is less dilatation than previously. I can only say I have never seen such a sequence of events, and rather think that the error arises from a failure to recognize the degree of dilatation at the first examination, or else from the incorrect recalling of the state of affairs existing then, compared with the actual condition found at the time of the second examination (possibly because of two different examiners with different nomenclature).

Contracted Pelvis

In his analysis Miller found that dystocia from disproportion, due mainly to contraction of the pelvis, accounted for almost a third of his cases. While in my series there were 46 cases (30 per cent.) with contracted pelvis, I do not agree that it was the sole cause of the failure of delivery. In only 21 cases (13 per cent.) was I able to find no other etiological factor than that of the contracted pelvis. In the remaining 25 cases there was always a combination with abnormal presentation (mostly occipito-posterior) or undilated cervix, and in not a few the three conditions were present together. In many cases the head was still found to be freely floating above the brim of the pelvis on the admission of the patient to hospital. I would emphasize once again that it is never correct to apply forceps to a floating head; very rarely even is the correct procedure adopted where the operation of so-called "high forceps" has to be resorted to at all.

In certain other cases the head was engaging in a satisfactory manner, descent was even proceeding, and had the forceps been withheld a little longer a satisfactory termination would have occurred without their aid. This is conclusively demonstrated by the large number of cases which, in fact, did terminate spontaneously after time was allowed to elapse, following an unsuccessful attempt at forceps delivery.

I do not intend to discuss the varieties of pelvic contraction which offered *difficulties*, but rather to show that pelvic contraction alone is by no means the commonest cause of failure. Possibly this is the commonest reason given by the unsuccessful obstetrician to explain the cause of failure, and not, perhaps, without good reason, because the force necessary to extract a child through a normal pelvis, where the presentation is posterior or the cervix undilated, is often greater than that required to deliver a child through anything less than the greatest grade of contracted pelvis, and this leads to impaired judgement in defining the cause of failure where much force has been exercised.

Occipito-Posterior Presentation

We are now brought to that potent source of failure, occipito-posterior presentation of the vertex. In no fewer than 48 cases (31 per cent.) there was an occipito-posterior presentation which, for the most part, had been unrecognized. In 16 cases occipito-posterior presentation was the sole cause of the failure. I think that the commonest obstetrical condition for which I am called out in the midwifery side of my consulting practice is labour complicated by this condition.

Occipito-posterior presentation is by no means easy to diagnose, and it is often necessary to introduce the whole hand into the vagina in order to arrive at a conclusion as to the exact situation of the occiput. In so many cases the sutures and fontanelles are obscured by a large caput, and the old advice of feeling for the ears is by no means so simple as is often stated, because the ears are often flexed forwards and give rise to much doubt. I can instance more than one case in which I have seen an occipito-anterior presentation converted into a posterior before delivery was attempted. I have done this myself.

Miscellaneous Factors

Other conditions which were discovered as the cause of the difficulty include eleven face and brow presentations, three breech presentations, four transverse lies, two cases where tumours were obstructing delivery, and certain abnormalities of the child, such as large child (over 12 lb., three cases), and four hydrocephalic monsters.

TREATMENT

Coming now to the question of treatment in these cases where difficulty is encountered, we must *consider* it from two standpoints. First, I will describe the method by which delivery was ultimately effected after a first attempt at delivery had failed, and then outline certain general observations in the conduct of cases where difficulty is likely to occur should forceps be attempted. In other words, I shall rather reverse the usual way of discussing treatment, and leave the question of prophylaxis until I have dealt with the *modus operandi* adopted.

In 33 cases of the 154 (20 per cent.) a spontaneous delivery was brought about by merely waiting, in these cases until the cervix had dilated or an occipito-posterior presentation had rotated itself forwards. This figure, I feel sure, would have been considerably larger [illegible]

the attempts at delivery been prematurely made in many of the cases, and I would particularly refer to those cases where artificial rupture of the membranes had failed to augment the pains and induced inertia. It is strikingly evident that one of the potent causes for the cessation of labour pains is artificial rupture of the membranes during the first stage of labour, and this is made still worse by exhaustion induced in the mother with unsuccessful forceps application, particularly where this has been done without an anæsthetic. Without intervention, quite a number of cases delivered by forceps or craniotomy would have terminated spontaneously except for inertia, for it must be remembered that the thrust of the uterus in a patient with good contractions is infinitely more effective than where this force is lost and delivery is being brought about by traction alone. For one thing, the force is directed more evenly on the whole of the child's body, and is thus distributed to the entire circumference of the presenting part, whereas with forceps there is a less even distribution of force, with consequent less effect on advance, and greater danger to both mother and child.

In 64 cases in all (42 per cent.) forceps were used to bring about the desired result. This includes 25 in which manual rotation of a posterior into an anterior vertex was first of all resorted to. In many cases the forceps had been applied more than once, and often, I might add, more than one attempt was again made before delivery was brought about after admission to hospital.

In these cases it was usually a combination of circumstances that led to failure. Some of them were cases in which forceps was the incorrect line of treatment in any event; I refer to those in which forceps had been applied where the disproportion between the child and the pelvis made it impossible to expect the delivery of a living child; in many of these cases this was complicated still further by posterior presentation or non-dilatation of the cervix. A preliminary accurate diagnosis would have led to the adoption of other methods of treatment. Why, then, were further attempts made unsuccessfully in hospital after a preliminary failure? The reason was determined by other considerations—namely, whether immediate intervention, in the interest of the mother or child, was desirable, and whether the condition of either was such as to forbid Caesarean section.

In many cases there were tears and lacerations of perineum, vagina, and cervix, which precluded any possibility of a section, because of the grave risks to the mother of peritonitis, with its almost invariable fatal issue. In other cases the child's heart was failing, shown by irregularity and slowing, and at times depressed fractures of the skull were palpable vaginally. In these cases we were faced with the alternatives: Caesarean section with the possible delivery of a dying child whose hope of survival was very slight; craniotomy performed on a living child; or forceps delivery with further risk of failure; and, I should also add, an unsatisfactory version. Which method to adopt is indeed a grave decision to make. The operation performed varies with individuals and different units, but in the Jessop Hospital it is uncommon for Caesarean section to be chosen. Even with what is said to be the safer lower uterine segment incision, there are few cases in which the decision to perform Caesarean section is justified either on account of the conditions found on examination or the dire results which would follow its universal adoption. For my own part, I should hesitate to do a craniotomy on a living child (in fact, on only two occasions have I purposely done this, and both of these were foetal monstrosities). What, then, is to be the position where the only alternatives are forceps or version (excluding a few rare cases suitable for pubiotomy or vaginal hysterotomy)?

Version at one time was much more employed than nowadays, for various reasons. Caesarean section is a safer operation than it was when version had its vogue, but in the cases under discussion both are dangerous. However, I think that in those cases where version is likely to meet with success without much danger to mother or child, Caesarean section is equally suitable, less damaging to the mother possibly, and certainly to the child. The result of dragging on a dying child with forceps will generally seal its fate, and certainly endanger the mother. At the same time, a successful result is brought about in a sufficient number of cases to make this, in my opinion, the method of choice, except in those cases where the disproportion is so great as to make it a certainty that even if the child can be delivered at all it will undoubtedly be dead, when I would prefer to take the risk of a lower uterine segment Caesarean section. I know there are others who will disagree with me and argue that where the chances of a living child being delivered by forceps are so trifling as to be almost negligible, it would be better to perforate at once. But where this combination of circumstances exists, the operation of craniotomy, grave at any time, is almost as likely to be succeeded by as serious a result to the mother as is Caesarean section.

I have already referred to the 25 cases in which forceps delivery was effected after manual rotation of an occipito-posterior presentation. In most of these cases the cause of slipping of the blades had been due to this posterior presentation alone. In a few cases the condition was complicated by pelvis contraction, and in others by an undilated cervix, but in the majority of cases a diagnosis had not been made of the posterior presentation, and usually after manual rotation, which was not always easy, the subsequent delivery became simplicity itself. Many of these cases would have spontaneously rotated forwards if enough time had been allowed, but a new complication of inertia had been induced by premature attempts to terminate the labour.

Delivery was effected in 38 cases (25 per cent.) by craniotomy, and to this might be added three cases of decapitation, where forceps had been applied to a transverse lie. In not all of these cases was it necessary to resort to craniotomy on account of disproportion between child and pelvis, as this would embrace nearly the whole number in the series in which the pelvis was contracted (46). This method of delivery, however, was chosen in many cases to bring about the delivery of an already dead child where, for example, the cervix was not sufficiently dilated to transmit the child, and expediency was urgent on account of the mother's condition.

In certain cases a reduction in the size of the child will cause less ultimate serious damage to the mother than by waiting for full dilatation of the cervix, or by a difficult high forceps delivery. I refer to cases where on account of risk of sepsis Caesarean section is precluded and the cervix is undilatable or where pelvic contraction is too great for a normal child to pass. In only nine cases was Caesarean section resorted to, four of these being by the lower segment route, four mothers died, four became septic, and two children died (two of the septic mothers were cases of lower segment incision). This is an indictment against this method of delivery after failed forceps, except in a very few cases.

Beyond a few immediate remarks, I would prefer to leave the question of prophylaxis until the general summing-up, particularly under the heading of ante-natal care. In eleven only of all the cases had ante-natal examination been made prior to the delivery; this number included two in which previous Caesarean sections had been performed for contracted pelvis, and one where

labour was obstructed by a large tumour, which only goes to show that where ante-natal examination has been made with a view to guidance in the subsequent delivery, the information obtained should be acted on. I will refer to this more fully again.

The End-Results

The immediate results in this class of case indicate an alarming mortality, both maternal and infantile. There was a tragic number of maternal deaths, an even larger number among infants, and such a morbidity rate as can hardly, I think, be presented by any other series of cases included under the heading of childbirth.

Twenty-one mothers died in the hospital (14 per cent.); two of these were undelivered, and three others must be added to this figure as having died in other institutions as an immediate result of the serious confinement. Of the 130 remaining cases, no fewer than 33 (25 per cent.) were morbid according to the B.M.A. standard, and 19 others were notifiable as pyrexial. If the fatal cases are added to the morbid and pyrexial we obtain a figure of 76, leaving only 78 which could be said in any way to pursue an uninterrupted puerperium. If from this 50 per cent. of the cases which apparently presented no grave termination immediately be deducted all those in which there was ill-health in mind and body in after years, we are left with a startlingly small figure to represent the women who had a confinement and suffered no detriment to their health as a result of it.

No fewer than 43 (29 per cent.) of all the infants were already dead before the patient was admitted to hospital. Seventy-nine of the infants were stillborn, and five died in the first few days (two were undelivered), thus leaving only 66—that is, 48 per cent.—who left the hospital alive.

I followed up the after-history of almost all of the mothers. It would be illuminating to know how many of the infants survived the first year of life, how many died subsequently, and how many show permanent impairment of function as a result of their stormy passage into this world. Not a few, where I was able to obtain information, still have gross lesions, such as depressed fractures and paralysis of the face or limbs, but if cerebral haemorrhages occur with such obvious evidence, there must also, I should imagine, be a group in which the damage occurred not in the pre-Rolandic area or communicating motor tracts, but in the silent areas of the brain and its association tracts.

From what has been said under immediate results, it follows that one has to be very guarded in the prognosis of either mother or child after the delivery has been executed, following a previous attempt in which forceps have been unsuccessful.

The puerperium was apt to be stormy, and often many weeks of ill-health were endured by the patient before discharge from hospital was possible. On returning home, large numbers of others required a long period of convalescence before being restored to anything like a semblance of their previous health, if, indeed, that were ever regained. Most patients suffered at least some damage—from varying degrees of ruptured perineum, vagina, or cervix, to the grossest examples of trauma involving the lower uterine segment, bladder, or rectum, leaving in their train vesico-vaginal and recto-vaginal fistulae, necessitating, later on, tedious, and often unsuccessful, operations.

I have followed out the end-results of all except fifteen of those patients who survived. I sent out a questionary to all who left hospital alive, and have received replies from the majority. Of these latter, I have examined practically every one with any complaint, and a large number of those who said they were well. Certain of those who said they had suffered in health showed on examination no pelvic lesion, but they were very few. Others, on the other hand, who said they were perfectly well, revealed pelvic disabilities, the extent of which makes it almost impossible to believe that life was not a burden. I have been struck forcibly during this investigation, years after patients have sustained serious damage, by the fortitude with which so many of them face, almost uncomplainingly, what would be to us crippling disabilities, apparently accepting the detriment to health as the normal consequence of child-bearing. In fact, I am sure that they must think that the curse of Eve does not refer to the labour alone, but is meant to continue throughout life.

In 54 cases of those followed up and traced the patient volunteered the information that she was perfectly well in health, and no ill effect was discovered. The remaining 58 all showed some local evidence of damage sustained at the confinement, and three have subsequently died of conditions not associated with the pregnancy. The injuries discovered were variable in character, but by far the largest group was made up of those women who had some degree of laceration of the cervix with ectropion of the mucous membrane, often associated with some vaginal prolapse and subinvolution of the uterus. This would appear to be the commonest sequel of disability. The laceration of the cervix, of course, is easy to understand, as also apparently the prolapse, but I am not perfectly certain that the prolapse is necessarily the result so much of stretching or tearing of the paracolpus, with its attachments, as a failure of the vagina to involute, due, possibly, to a septic state supervening on the delivery. Immediately after delivery the vagina is always lax, just as the uterus is always enlarged, and, to me, it would appear that any process deterring the involution of one organ will likewise leave the other in its subinvoluted condition. The vast majority of those cases in which vaginal prolapse was present had also some failure of involution persisting in the uterus, not only immediately or in the first few weeks after delivery, but months and years later.

Were we to carry out an investigation into the after-results of damage caused at a confinement, and particularly of sepsis, when many years have intervened, I am sure we should find that even a greater number of these women had suffered ill-health than would appear from an investigation into the after-results where the period of elapse had only been at most six years and shows 52 per cent. with some degree of ill-health. Possibly as a late result, those who had only slight injuries, or mild traces of infection immediately succeeding the labour, would evidence greater degrees of disability than those cases in which trauma or sepsis had been serious, because where serious injury has taken place the patients are usually looked after carefully during the puerperium and succeeding months until they have been restored to some semblance of good health. Gross tears of the vulva, vagina, and often of the cervix are repaired at once as a rule, and though many take a long time to heal, the patients remain under medical supervision and further operative procedures are adopted where necessary. Consider, for example, the woman with a vesico-vaginal fistula due to immediate damage or sloughing in the first few days. In those cases which do not heal spontaneously, as so many of them do, an operation is usually performed within a reasonable time, and, if unsuccessful, is repeated until the patient is cured of the disability. Most women with a complete rupture of the perineum have it sutured at the time, and if healing does not take place further operation is usually advised, and thus the patient is cured of her incontinence.

Likewise, the patient who has a very severe form of puerperal infection is treated continuously until well on

the road to recovery. Complications arising during such a stage of convalescence—for example, parametritis—are recognized and treated appropriately. It is regrettable that patients who sustain slight grades of trauma, such as small vaginal lacerations, trifling tears in the cervix, and minor degrees of sepsis, pass at times unrecognized into the large group which might be labelled "the invalid woman." It is almost as important to repair those small traumatic lesions as the grosser forms, since the latter will usually be treated before permanent ill-health and impairment of function have occurred. Many of the cases of sepsis, however, arise in those women who have only a minor degree of trauma, and often such sepsis would have been averted had the damage been recognized and repaired. A large group of women sustain at confinement a minor degree of sepsis which is overlooked. It is difficult at times to know how this can be obviated. The patient after a difficult confinement, such as occurs in almost all these cases of unsuccessful forceps, will naturally be more ill than her more fortunate sister who had a normal confinement, but beyond the fact that she may be kept in bed rather longer than usual, often nothing further is done to aid her recovery. The slight sepsis about which I am now talking occurs in those cases in which the temperature during the puerperium shows but little rise above normal. The attendant on a case of complicated labour perhaps sees the patient rather more frequently than usual during the first few days, is gratified to find that no serious sepsis has occurred, and the morning temperature which is taken in these cases will often show no rise above 98.4°, so that after the first few days daily records are no longer kept. It should be borne in mind that the temperature should be subnormal during the early days of the puerperium. These very patients, who only have an occasional rise in the evening temperature (pointing to a certain amount of sepsis, such as decidual endometritis), often fall into the category of those who fail to involute the organs normally and give no indication of this puerperal septic state until years later, when the subinvoluted organs cause trouble and stimulate a search for the origin of it.

One almost constant sign, pointing to a failure of involution of the uterus, is a persistence of the lochia beyond the normal period of ten days to a fortnight. In fact, so common is this that I am tempted to think that most women, even among the educated classes, are under the impression that loss should go on from six to eight weeks after delivery. We all know that this is not so if the uterus is involuting normally. The lochia, which may have diminished or ceased by the tenth day, are not commented on by the patient, who, beyond being a little pale and wan, as she expects, is thought to be recovering from the stormy labour and gets up. The same day, or the next day, loss again appears, and often goes on for days and weeks. This, I maintain, is the most constant sign of failure of involution of the uterus, and concurrently there is failure of involution of the supports of the uterus and vagina. One can see, then, how easy it is for vaginal prolapse and retroversion of the uterus to occur, and in a not inconsiderable number of the 60 to 70 patients whom I have examined from one to six years after the confinement in the series under consideration these conditions are present. A tenth-day examination of the patient vaginally, or one made before the patient is entirely discharged, would often have revealed this state of affairs, which could have been often remedied with appropriate treatment, though it hardly comes within the scope of this paper to discuss what that should be.

Other evidence of pelvic infection which I have found beyond this chronic subinvolution was such conditions as salpingo-oöphoritis, retroversion, and impaired mobility of the uterus, due to parametritis or pelvic peritonitis. I would like to say here that pelvic parametritis is a far commoner condition than is generally supposed. We all recognize the large effusion which spreads into the iliac fossa and on the abdominal wall like a "tea cake," but minor grades of the condition are much more frequently met with than I, at any rate, at one time imagined. The end-result of such cases of parametritis where suppuration does not generally occur, is scar tissue formation, which leads to fixity of the pelvic organs and distortion of the broad ligaments, with a blood circulation in the pelvis considerably impaired. Over and over again have I seen the train of ill-health associated with pelvic congestion and varicocele of the broad ligament follow scarring in the broad ligament, due to imperfect resolution of a pelvic parametritis arising in a case of sepsis, unrecognized because mild.

To proceed now with the sequels induced by this often too hasty attempt to precipitate what Nature meant to be a physiological process, we must consider the effect on future pregnancies and potentiality of child-bearing. Of those women in the 130 cases (154, less those who have died) whose after-histories I have followed, 37 have become subsequently pregnant. This figure includes four who are now pregnant, and three whose pregnancies terminated in abortion, while, for the rest, one or two have become pregnant on more than one occasion. Forty-one living infants have been born to them. When we take into account the fact that 82—that is, more than half the cases reviewed—were primigravidae when their serious confinement occurred, it follows that a considerable degree of sterility was the direct result of the labour.

PROPHYLAXIS

I have now recounted the etiology, treatment, and end-results of this series of cases of failed forceps, and, before closing, I would like to say a few words on how such a state of affairs can at least be improved, if not remedied. In the section devoted to treatment, most of what I said referred to the treatment adopted where the forceps had been unsuccessfully applied in the first place and the issue often determined before further treatment was instituted. I have deferred the discussion on prophylaxis, as the two factors involved were so different; in one case treatment had already begun and had to be proceeded with, while the procedure adopted would have frequently been so different in the other case, in which forceps application must have inevitably failed, and would therefore not have been resorted to had prophylactic measures been taken.

Ante-Natal Care

Ante-natal supervision undoubtedly would go far to prevent many of these cases of failed forceps, but certainly not all. So much has recently been said and written about the Utopia we are going to reach in midwifery by the establishment of a sufficient number of ante-natal clinics that the general public is becoming lulled into thinking that because a woman has attended an ante-natal clinic she is as good as delivered. In the first place, I would like to utter a mild word of warning against the use of the word "clinic."

The person who should carry out the ante-natal supervision of the pregnant woman is undoubtedly he who is going to see her through the confinement to the end of the puerperium. If the idea that a patient must attend a special clinic spreads too far, I feel sure that large numbers of pregnant women will not attend at all for ante-natal examinations, as they naturally resent what seems to them mass treatment, and many a patient who would put herself during pregnancy under the care of her

own medical attendant will be precluded from any supervision at all. I cannot too strongly urge that every doctor should fit himself for being an ante-natal clinician.

Too often, also, these clinics are supervised by public health officials with very little clinical experience, or by persons who never conduct a confinement at any time. Do not think that I am depreciating too harshly the good work done by many of these centres, as undoubtedly they have their place in the welfare of the community, but I consider they should be more in the nature of consulting clinics to which any medical man can refer his cases after he has made a preliminary ante-natal examination which he wishes amplified, or where he wishes for advice in the conduct of the labour. Each of these centres should have adequate facilities for the confinement of those women whose housing conditions are unsuitable or where the medical aspect of the case demands suitable convenience for major operations, and patients should be under the care or direction of the same person from start to finish.

If adequate ante-natal supervision was provided, I believe that a large number of these cases of failed forceps would disappear. But the keynote of success is the word "adequate." I have just said who, in my opinion, should exercise that supervision—the medical attendant who is to conduct the labour, guided, if need be, by advice from a consulting centre. Unless, however, the information gained at the preliminary examinations is acted on, then no reduction in the number of cases of failed forceps can be expected by ante-natal supervision. With this proviso, I think all will agree that most of those cases of failure could have been prevented where the etiological factors were dystocia due to disproportion, or tumours obstructing labour, or faulty presentations.

There remains, however, the group where failure to effect delivery was not the result of any condition present at the beginning of labour, and could not, therefore, have been prevented by ante-natal care—those 47 cases, for example, where an undilated cervix was responsible for the non-success. That many of these misfortunes should not have happened must be conceded. In some, the state of dilatation of the cervix had not been recognized, and possibly better teaching facilities will get over that to some extent—for example, when a student's three months' obstetrical practice is replaced by a six months' course.

In others of this group the fault often lay in a humanitarian desire on the part of the obstetrician to get a painful physiological process over as rapidly as possible. I am not saying this in a spirit of criticism, as I know how much greater are the difficulties under which the practitioner works than the consultant, and the consultant, too, is unduly influenced at times by this consideration to adopt measures which his considered judgement tells him are unwise. I hardly see how occasional mistakes of judgement can be prevented in this way, unless all patients are removed from the sphere of family influence, and better anodynes for use in labour are discovered.

I close with words of advice from the great Sydenham, about whom it was said that, when in doubt, he consulted his own reputation and the patient's safety by doing nothing, and it is certain that of all the aids we possess in the safe delivery of woman in labour, none is of greater value than the practice of the art of patience.

THE TREATMENT OF SECONDARY HAEMORRHAGE AFTER SUPRAPUBIC PROSTATECTOMY

BY

ANDREW FULLERTON, C.B., C.M.G., M.CH., F.R.C.S.I.

PROFESSOR OF SURGERY, QUEEN'S UNIVERSITY, BELFAST

Primary haemorrhage after prostatectomy can be easily and safely controlled by the various methods in vogue for arresting haemorrhage during and after this operation. The operation of Thomson-Walker, in which bleeding vessels are secured by ligature and oozing stopped by packing the prostatic cavity, and, as an alternative, the use of the haemostatic bag, are certain preventives. Secondary haemorrhage, however, is not so easily dealt with as primary, on account of the narrowing of the suprapubic wound, which takes place rapidly after the drainage tube has been removed. Those who have attempted packing the cavity in these circumstances will agree with me that it is a very difficult procedure involving a great deal of pain to the patient and trouble for the surgeon; besides, it may fail to accomplish its object unless an anaesthetic is administered and the suprapubic wound widely opened up.

For some time past I have been using a haemostatic rubber bag (see Fig. 5) which differs from the Pilcher bag in being spherical instead of pear-shaped. One objection to Pilcher's bag is that it enters the membranous urethra and stretches the compressor urethrae muscle, causing temporary or permanent incontinence. The improved bag, being spherical in shape, can be made to fit accurately into the prostatic cavity, and cannot enter the membranous urethra. It was first made for me by Messrs. Mayer and Phelps, and has stood the test of many trials in the prevention and treatment of primary and secondary haemorrhage.

I need not enter now into the preventive treatment of secondary haemorrhage after prostatectomy, which is due to sepsis and sloughing, and may take place from any of the raw surfaces left after operation, particularly from the margins of the mucous membrane at the entrance to the prostatic cavity and from the cavity itself. Rigorous aseptic technique during and after operation will, no doubt, lessen its incidence, but a wound communicating with the surface easily becomes contaminated, and an aseptic course is impossible. Efforts will, of course, be made to render the raw surfaces as clean as possible, but, notwithstanding all precautions, secondary haemorrhage will occur in a certain proportion of cases. During the years I have been in practice I have had cases occurring from time to time, and in the last few months I have had two: one commencing on the thirteenth day and one on the fifteenth. Both patients were poor risks, and quite unsuitable for any prolonged procedure, either at the primary operation or subsequently. In both the haemorrhage was immediately arrested with very little discomfort by the method I am about to describe, and both have made good recoveries.

It is better to anticipate trouble in these cases by inserting the bag at the very first appearance of haemorrhage, before the bladder has had time to fill with clot and before much blood, that can ill be spared, has been lost. There are generally several prodromal attacks of slight haemorrhage before the ultimate burst appears. It is well to be forearmed.

METHOD OF ARRESTING SECONDARY HAEMORRHAGE

A catheter is first passed into the bladder—a soft rubber by preference—but if this does not enter easily a [illegible] elastic may be used. Through the suprapubic [illegible]

light forceps, such as Desjardin's gall-stone forceps, is then introduced, and the catheter gently felt for. As a rule the latter can be easily seized by the forceps and brought out of the wound (see Fig. 1). It may be necessary to introduce the finger to locate the catheter, but this should be avoided, if possible, as it causes a good deal of pain. The urethral tube of the haemostatic bag is then pushed over the end of the catheter and secured by tying round both a piece of linen thread or any available substitute (see Fig. 2). The tube and bag are then smeared thickly with melted sterile vaseline to facilitate withdrawal of the urethral tube and to prevent the bag from becoming unduly embedded. The catheter is then withdrawn through the urethra, bringing the bag, which is thin and collapsible, into position (see Fig. 3). The bag is then distended by filling it with water. When distended it bulges over the edges of the prostatic cavity and makes contact with the walls of the latter, so that pressure can be exerted on both by light traction at the urethral end (see Fig. 4). This pressure is kept up by attaching a weight to the tube emerging from the urethra by a piece of cord, which can be brought over the foot of the bed. The bag must not be over-distended, otherwise it will not fit snugly into the prostatic cavity, but press on the base of the bladder, and may even, if large, exert injurious pressure on the ureteric orifices. The bag is kept in position for two or three days, but is not finally removed until it is judged that all risk of haemorrhage has ceased. It may be allowed to collapse and remain in the bladder as a precautionary measure. Meanwhile, the urethra is irrigated by the side of the tube now acting as a tied-in catheter, using silver nitrate, potassium permanganate, or other suitable solution. This minimizes the risk of urethritis from the presence of a foreign body.

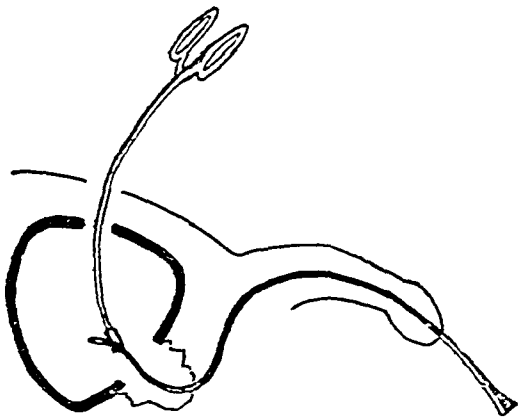

FIG. 1.—Catheter introduced into bladder and grasped by forceps.

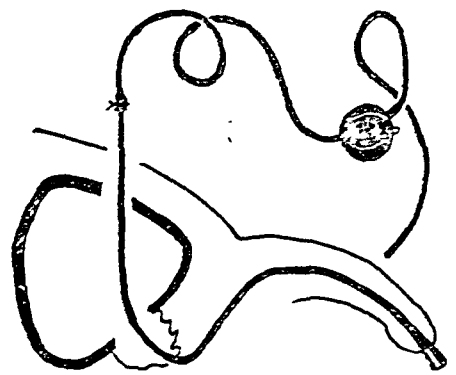

FIG. 2.—The urethral tube of the haemostatic bag is attached to the catheter.

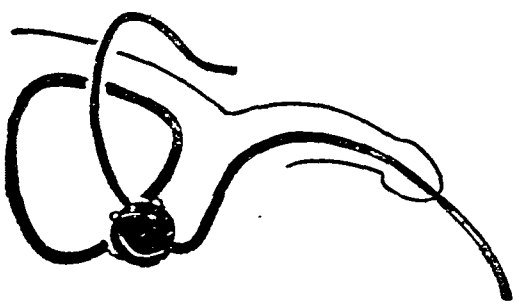

FIG. 3.—The bag in position before inflation.

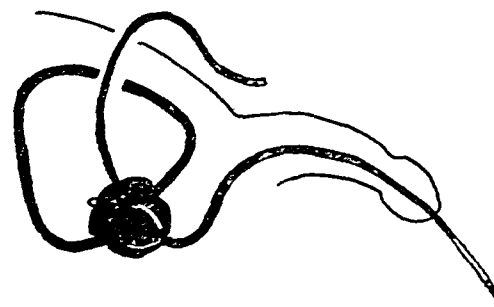

FIG. 4.—On distending the bag with water, pressure is exerted on the cavity and its margins.

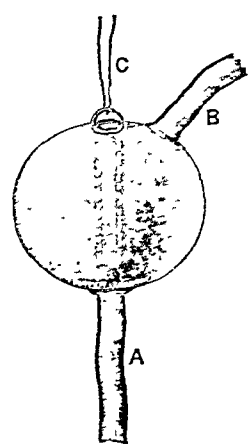

FIG. 5.—Haemostatic bag.

This precaution I always adopt when using the in-dwelling catheter. When it has accomplished its purpose, the bag may be removed easily through the suprapubic wound. To prevent infecting the bladder by drawing the exposed part of the urethral tube, which may be contaminated, back through the urethra, the bag may be cut off close to the meatus before removal.

COMMENTARY

This method of arresting secondary haemorrhage is comparatively painless, is simple and efficient, and I have yet to see any deleterious effect. The same method may be used for reactionary haemorrhage. The haemostatic bag, being globular in shape, fits snugly into the prostatic cavity, and is superior to the pear-shaped Pilcher bag commonly in use. The bag is made in three sizes. For a very large prostatic cavity it might be advisable to have outsizes made. With this apparatus in his possession the surgeon need have no anxiety about his ability easily and rapidly to arrest haemorrhage after prostatectomy, either primary or secondary, and, from my own experience, I am satisfied that he need not anticipate any untoward after-effects.

I am indebted to my former house-surgeon, Dr. R. W. M. Strain, for the illustrations, and to Messrs. Maw and Pledge for the blocks of Figs. 3 and 5.

CONSTIPATION AND RIGHT-SIDED PTOSIS *

BY

By J. V. FIDDIAN, M.D.CAMB.

ASSISTANT SURGEON, ASHTON-UNDER-LYNE INFIRMARY

There are few subjects on which medical views have changed more radically during the present century than on constipation. The haggard faces and emaciated frames of the victims of Arbuthnot Lane's "kinks" are now recognized as the stigmata of chronic cascara poisoning, and we spend our days combating the precepts of our medical forebears, and in persuading people to leave their harassed bowels alone. Among those who have contributed to the establishment of the modern view two names stand out, Hurst and Alvarez.

Hurst was the first to describe the gastro-colic reflex, by the operation of which the entry of food into the stomach is followed by mass peristalsis in the colon. This peristalsis, or mass movement, as it is better called, is a remarkable phenomenon of the large intestine, unlike any of the movements of other parts of the alimentary canal. It occurs only three or four times a day, and results in the sudden transference of large blocks of colon contents from one part of the colon to the next, or even from one end of the colon to the other. First observed radioscopically by Holznecht and later studied by Hurst and by Barclay, its exact mechanism is still not clearly understood.

It has never been observed by the naked eye in man, but Alvarez, having filled the colon of a cat with a solution of soap, and then ligatured the rectum, saw "the whole colon shorten and straighten." The manner of entry of the small intestine into the large, and the presence of the ileo-colic valve and sphincter, confer a closed end on the proximal portion of the colon. When the colon shortens by the action of its longitudinal fibres, the blind proximal end, acting like the piston of a syringe, propels part of the contents of the ascending colon round the hepatic flexure into the transverse colon. On the subsequent relaxation, the hepatic flexure breaks the column of faeces and prevents the displaced portion of it from slipping back. When mass movement occurs in the distal half of the colon the natural result is defaecation, but the capacious rectums of dyschezic individuals receive the addition to their contents without response.

Hurst's second great contribution to our knowledge of constipation was his division of the condition into dyschezia and colonic stasis.

DYSCHEZIA

Dyschezia is simply the imperfect functioning of the rectal reflex. It is not so much a disease as an adaptation to civilized conditions of life. Even domestic animals suffer from it; the process of house-training of a dog is merely the painstaking abolition of its rectal reflex. Hurst found that the rectal reflex is excited by sudden increase of pressure in the rectum, normally produced by the entry of faecal material from the pelvic colon. By inserting a balloon into the rectum, and inflating it slightly, he was able to produce a brisk rectal reflex. If the balloon was allowed to remain inflated, it ceased in a short while to excite the reflex, and a further inflation was required to excite it anew. By successive stages of inflation he could induce the rectum to tolerate a pressure enormously greater than that which originally excited the reflex. This is exactly what happens in dyschezia. The rectum becomes tolerant, and finally acts as a collecting tank, much as the bladder does for the kidneys. Unfortunately the evacuation of the rectum is not, in the present state of our evolution, under voluntary control, so the parallel breaks down.

Probably all civilized humans, those who live in cities at any rate, have some degree of dyschezia. It would be highly inconvenient otherwise. It is quite compatible with perfect health; at the worst it is responsible only for such troubles as anal fissure and haemorrhoids. Absorption of toxic material does not occur from the rectum, and in any case the faeces by the time they reach the rectum are comparatively detoxicated. The literature of constipation abounds with instances of people whose bowels did not move for weeks and even months at a time, and yet whose health did not materially suffer.

The vast majority of patients who come complaining of constipation are suffering from dyschezia. When a purgative is given to a dyschezic, all the intestinal movements are accelerated, and the dormant rectal reflex is at length excited by rapid addition to the rectal contents. In other words, the whole complex business of intestinal digestion and absorption is disordered in order to fill the rectum to the threshold of stimulation. The terminal portion of the small intestine contains highly toxic material. Nearly all the valuable products of digestion have been absorbed and the residue abounds in chemical and bacterial poisons. This toxic fluid is normally dealt with in the caecum and ascending colon, where it is detoxicated by dehydration.

This reabsorption of water is also a valuable element in the fluid economy of the body. Purgatives interfere with this process, and insufficiently dehydrated material is carried through parts of the colon which have not the caecum's power of selective absorption. Toxins may be absorbed beyond the power of the liver to detoxicate; foul tongue, headache, and disordered digestion may result. The most logical method of dealing with dyschezia is the periodical simple enema, but it is not very reasonable to train the rectum to act as a tank and then knock it about for so doing.

COLONIC STASIS

Various types of stasis in the colon have been described, but most of them are very rare. Barclay, from long experience of radiology, declared that, apart from mechanical obstructions, there are two, and only two, sites where stasis occurs—the caecum and the rectum. Caecal stasis deserves serious consideration. It is not nearly so common as dyschezia, but is nevertheless fairly prevalent. How can it be diagnosed? Hurst studied the rate of passage of the intestinal contents in normal individuals, and laid down certain criteria. One of these was that caecal stasis was probable, if twenty-four hours after a barium meal most of the barium was still in the caecum. He also observed that the caecum in a normal individual was empty in the morning. Chyme only begins to pass the ileo-caecal valve three or four hours after the morning meal. If a patient at the morning surgery has a distended caecum, caecal stasis can be diagnosed. During the years I examined in this way every panel patient who came to me complaining of constipation or abdominal symptoms of any kind. I found 23 men and 72 women suffering from caecal stasis; this amounted to 4.2 per cent. of the men and 14.1 per cent. of the women on my panel.

Caecal stasis, then, is fairly prevalent, and is three times more common in women than in men. There is reason to believe that it is much more common even than

* Read before the Ashton-under-Lyne Division of the British Medical Association, March, 1931.

these figures would indicate, for they represent only those with caecal stasis and some abdominal complaint. It is noteworthy that persons with caecal stasis do not complain of constipation unless they have dyschezia as well. They will aver that their bowels move normally, though the matutinal examination reveals a boggy distended caecum.

Dyschezia is relatively harmless; can the same be said of caecal stasis? There are not wanting physicians of eminence who hold that view. Geoffrey Evans, in a recent paper, quoted the experiments of Alvarez, and asserted that the normal condition of the bowel is to be full and not empty. Alvarez administered barium to a number of normal individuals, and recovered it quantitatively from their faeces. He found that only 50 per cent. was recoverable in the first three days, and that the excretion of the remainder occupied several more days. The same results were obtained when glass beads were used instead of barium. It appears that the complete passage of the intestinal canal is a more protracted process than was formerly believed. Nevertheless, other abdominal conditions are so frequently found in association with caecal stasis that some causal relation seems an irresistible conclusion. Kantor, Schector, and Marks, three American radiologists, found on examining their records that caecal stasis in a normally disposed caecum was not usually associated with symptoms of marked clinical importance, but, when present in a low caecum, it was much more frequently productive of symptoms. I approached the subject the other way round, but arrived at the same result, for I found that in thirty-seven persons who clinically had caecal stasis and abdominal symptoms, every one when examined radiographically or subjected to operation proved to have an abnormally low caecum.

The question of the position of the caecum and ascending colon has been gradually assuming importance during the past quarter of a century, since Wilms in 1908 pointed out that removal of the appendix failed to cure many cases of right-sided pain, and that these cases all appeared to have undue mobility of the caecum. Many writers have since given the subject attention, but the outstanding British contributions have been from Waugh and Carslaw. Waugh in 1920 reported on a series of 180 cases of operation for the relief of right-sided ptosis, and Carslaw in 1928 described a series of 248 cases treated by Waugh's method, and discussed the whole subject very thoroughly.

The colon in quadrupedal animals is suspended in its whole length from the dorsal abdominal parietes by a mesocolon. Undue tension on this mesocolon is prevented by the support of the anterior abdominal wall. Man, in assuming the erect attitude, incurred certain disabilities unknown in the animal world, such as varicose veins, haemorrhoids, and femoral and inguinal hernia. The intestines also were assailed by the pull of gravity in a direction at right angles to that which they were designed to face, and it is not surprising that certain modifications in peritoneal arrangements have appeared in the course of the further evolution of the human race. That must surely be the explanation of the fixation of the human colon to the parietes at various points. The process can be followed in the human embryo from the wholly free to the partially fixed condition.

Just as the rotation of the colon is sometimes incomplete, so that the caecum lies in the mid-line or even to the left, in the same way (but much more frequently) the fixation of the colon falls short of the usual adult condition. So far as the descending colon is concerned, its fixation, by fusion of its mesentery with the posterior parietal peritoneum, is practically constant. But the ascending colon is only securely fixed to the parietes in 75 per cent. of cases; mobility of the right colon is therefore a congenital condition. Treves found it in 26 per cent. of bodies examined, and Pirie in 20 per cent. of the bodies of children. Recently Larrimore in America has made radiological studies of babies 1 day old, and found that the incidence of mobility of the right colon was identical with that of any other age group. It would appear, therefore, that man's adaptation to the erect attitude is not yet complete.

Controversy has raged on the question as to whether the possession of a ptosed right colon is a disadvantage. Hurst declared that a ptosed right colon is found as frequently in healthy people, with perfect digestion and no constipation, as in the constipated. It is certain that numbers of persons with mobile right colons make no complaint of abdominal symptoms. There must be 325 prolapsed colons on my panel. During three years only 95 persons made complaint which led to the diagnosis of caecal stasis, and only 37 of these cases were sufficiently serious to merit *x*-ray examination or operation. The striking fact is, and this is my contribution to the study of this question, that all those 37 persons were found on investigation to have prolapse of the caecum and ascending colon. Out of 975 individuals with a normally fixed colon during three years no case arose requiring operation for an abdominal complaint; out of 325 with prolapsed colons in the same period there were 37 whose pains and disabilities, I will not say "demanded" operation, but were sufficiently severe to lead them to consent to it.

A surgical colleague recently declared that every woman had a mobile ascending colon; he meant, of course, that every female abdomen he opened showed this condition, and he was right. It is the custom now, when operating for duodenal ulcer or gall-stones, to remove the appendix. How often does a separate incision have to be made? Only once have I had to make it. If the appendix can be removed through an incision, the lower limit of which is at about the level of the umbilicus, there must be some abnormal mobility of the caecum. Carslaw has pointed out the steps by which the drag of a loaded colon lacking support from the parietes produces effects in turn on the right kidney, the gall-bladder, and the duodenum, with all of which it is closely connected. Both Waugh and Carslaw described types of cases with symptoms simulating those of other abdominal diseases, which at operation were found to have nothing but right-sided ptosis. The failure of many abdominal operations to relieve the symptoms they were intended to relieve has been due to failure to recognize this fact.

Confusion is particularly liable to arise with appendicitis. In a series of 21 cases of right-sided ptosis I had operated on three years ago, five had had the appendix previously removed without relief, and in five others a definitely pathological appendix was found at my operation. The only thing that can be said with certainty in this connexion is that right-sided ptosis is frequently associated with appendicitis, and that, when it is, failure to fix the colon may lead to a relative failure of the operation to relieve the condition for which it was performed.

If a prolapsed right colon is so disadvantageous, how is it that only 10 per cent. of persons so afflicted complain of symptoms? It has to be remembered that about a third of each twenty-four hours is spent in a recumbent position, so that the lack of support for the colon is only operating for sixteen hours out of the twenty-four. Further, in muscular individuals, with firm abdominal walls and high intra-abdominal pressure, the abdominal viscera are packed like prunes in a bottle with little or no tendency to change their relative positions. Those who do complain of symptoms are typically females with certain physical charac-

teristics which constitute the well-known "faulty development of the infantile type." They are often undersized and thin, with poorly developed mammae, a long thorax, and an acute subcostal angle. Another fairly common type is the maternal—women whose abdominal walls have never recovered from the stretching of pregnancy.

It is the conjunction of caecal stasis with inadequate support for the caecum which apparently determines the onset of symptoms. The sympathetic nerve supply to the bowel is carried to it in the walls of the blood vessels. The sympathetic, it will be remembered, inhibits bowel movements and closes the ileo-colic sphincter. The theory of Tyrrell Gray and Carslaw is that, when the loaded caecum descends into the pelvis, traction is made on the vascular pedicle, which is the most resistant constituent of the mesocolon. The sympathetic nerves are stimulated by the traction, and the bowel movements are inhibited; stasis increases, the drag and the stimulation are augmented, and so the process continues in a vicious circle. In some of my own cases I have seen the bundle of vessels which run to the ileo-caecal angle standing out like a rope, and obviously supporting the weight of the colon.

The operation of colopexy, as devised by Waugh, seeks to imitate nature, and to confer on the subject of right-sided ptosis the same degree of fixation of the colon as his more fortunate fellow humans have at birth. After the appendix has been removed, an incision is made into the peritoneum in the angle between the ascending colon and the flank. A pocket is made by stripping up the peritoneum from the flank; the colon is rolled into this, and made secure by sewing the peritoneal flap over it. The bowel is thus in contact over a broad area with retroperitoneal tissues, and the adhesions which it there forms are the important element in its fixation. There is no technical difficulty in the operation, provided that a sufficient incision is made. I always use a paramedian incision to avoid weakening the abdominal wall, though the wide retraction entailed is responsible in some cases for a fair amount of after-pain. I have performed the operation fifty-three times, and have had no untoward complications and no deaths.

The results in some cases have been dramatic. In one case the most careful preparation in the ward had failed to remove all solid faeces from the caecum. The day after the operation, for the first time that this patient could remember, her bowels moved naturally, and have continued to move without purgatives ever since. About thirty of my cases have been from my own panel, and the happy result has been that many who were formerly most troublesome cases now make infrequent appearances.

It must not be forgotten that dyschezia is as likely to be present after the operation as before. Caecal stasis also may occur, but it causes no pain. Some of my cases radiographed after the operation show only slight elevation of the colon compared with the previous condition, and moderate caecal stasis; yet they have been relieved of their symptoms. This observation harmonizes with the theory of Tyrrell Gray and Carslaw, for if it is the traction on the mesocolon which causes the pain and the stasis, then a very small lift and fixation is sufficient to relieve the trouble. If a man is hanging by the neck, a lift of an inch or so will save his life.

As the result of the study I have given to this subject I have formed the opinion which I have tried to justify in this short paper that the vast majority of pathological abdominal conditions occur in that quarter of the population who have congenitally ill-supported colons. A timely colopexy would relieve their early symptoms, and save them subsequent visits to the operating theatre for much more serious operations.

THE SOURCE OF INFECTION IN A MINOR OUTBREAK OF PUERPERAL FEVER

BY

C. G. PAINE, M.B., B.S.LOND.

The two cases of puerperal pyrexia to be described occurred at close intervals of time at a nursing home in a town. The home had been until then singularly free from sepsis. Both patients were infected with haemolytic streptococci and, in addition to the rise in temperature, presented one unusual feature in common—namely, multiple suppurative arthritis. It was thought possible that the two organisms might be identical, and that there was present a common source of infection responsible for both cases.

King[1] showed that there is a well-marked correlation between the presence of haemolytic streptococci in the upper respiratory tracts of medical attendants and the incidence of cases of puerperal fever. Subsequently, Smith,[2] by means of agglutinin-absorption experiments, showed that, out of eighteen cases of haemolytic streptococcal infection during the puerperium, the source of infection could be traced in eleven to the throat or nose of the doctor, student, or nurse in attendance.

CASE I

Mrs. X was admitted at 3.30 a.m. on June 18th, 1931. Vaginal examination was made by Sister A on admission and again at 6 p.m. on the same day. At 7 p.m. a vaginal examination was performed by Dr. B; the perineum, etc., was prepared by Sister A and Nurse C, and a low forceps delivery was made by Dr. B. During delivery the perineum was lacerated. The following evening the patient had a rigor, temperature rising to 104° F. on June 19th. Daily rigors followed; suppurative arthritis developed in the right shoulder and wrist, and in the right knee. The patient ran an intermittent temperature, and died at the end of three weeks.

No face masks were worn by any of the attendants either before or after delivery.

Bacteriological Findings.—Throat, negative for haemolytic streptococci; urine, sterile; cervix, coliforms and haemolytic streptococci; perineum, negative for haemolytic streptococci; blood, shoulder, and knee, positive for haemolytic streptococci.

CASE II

Mrs. Y was admitted at 3 a.m. on June 21st, 1931, and spontaneous normal delivery took place at 4 a.m. No vaginal examinations were made before delivery. Sister A only was present at delivery, and she wore a mask. Nurse C relieved Sister A at 6 a.m., and subsequently did all the nursing of this patient until June 27th, when Sister A attended her. Rigors commenced twenty-four hours after delivery, and occurred daily, with high temperature between. Within a week the patient had developed suppurative arthritis in the left sterno-clavicular joint and in the right wrist-joint. After two weeks her condition slowly improved, and the temperature settled after about eight weeks.

No masks were worn by Nurse C up to the time the patient had developed a temperature.

Bacteriological Examinations.—Haemolytic streptococci found in throat, vagina, and blood; urine, sterile.

HISTORY OF CONTACTS

Dr. B delivered Mrs. X only. During the week before and the week after delivery of Mrs. X Nurse C had delivered, had been present at the delivery of, or had nursed during the puerperium, five other women. At Mrs. X's delivery masks were worn. All five had uneventful puerperia. Sister A also dealt with three of these and wore a mask while attending each. They also had uneventful puerperia.

Bacteriological Findings from Throats of Possible Carriers.—Sister A (present at both deliveries), positive for haemolytic streptococci; Dr B (present in Case I), negative for haemolytic streptococci; Nurse C (assisted at both cases), positive for haemolytic streptococci; maid (in attendance on both Sister A and Nurse C), positive for haemolytic streptococci (This maid was suffering from acute tonsillitis.)

Where available, two separate colonies of haemolytic streptococci were picked off the culture plates to initiate strains for investigation. The strains for convenience were labelled as follows:

Strain A	Nurse C	Throat
Strain B	Nurse C	Throat
Strain C	Sister A	Throat
Strain D	Sister A	Throat
Strain E	Mrs. Y	Throat
Strain F	Mrs. Y	Vagina
Strain G	Mrs. Y	Vagina
Strain H	Mr. Y	Blood
Strain I	Mrs. X	Blood
Strain K	Maid	Throat
Strain L	Maid	Tonsil

Technique

With a view to identifying the strains from possible carriers with those present in the blood of the patients agglutinin absorption experiments were performed. The technique adopted was that used by Smith.[2] Agglutinating serums were prepared by immunizing rabbits with killed emulsions of strains H and I. The titres of the serums prepared were 1 in 2,000 for the homologous strains. For the agglutinin absorption tests 0·02 c.cm. of serum was absorbed with the deposit obtained after growing each strain in 50 c.cm. of 10 per cent. ox-serum broth for forty-eight hours at 37° C. These cultures were enumerated by counting against red blood cells, and contained approximately 500 million cocci per c.cm.—that is, 0·02 c.cm. of serum was absorbed by 25,000 million cocci. The deposits in each case were made up to 0·18 c.cm. bulk, so that the final dilution of the serum in absorption tests was 1 in 10. All absorption tests were first incubated in water bath at 37° C. for four hours and then left overnight at room temperature. In order to obtain stable suspensions for agglutination with the homologous serum the strain was repeatedly subcultured in 50 c.cm. of beef-heart broth (*p*H 7·4) for twenty-four hours. The culture was then centrifuged for a very short period, and, if the broth was sufficiently turbid, then one volume of emulsion was added to one volume of normal saline in a Dreyer's tube and incubated in water bath for two hours at 55° C. If no spontaneous agglutination occurred the emulsion was then tested against the homologous antiserum to determine its sensitivity. From seven to nine subcultures were necessary to obtain strains in a suitable condition for the tests. All agglutination tests were incubated in water bath at 55° C. for two hours before being read.

Commentary

From the history it was possible that either Sister A or Nurse C could have been the carrier. The maid, who was suffering from tonsillitis and from whose throat haemolytic streptococci were recovered, came into daily contact with both Sister A and Nurse C, but not with the patients. It was possible that the maid may have infected either Sister A or Nurse C, one of whom subsequently could have carried the infection to the patient.

From the above tables of agglutination-absorption tests it appears that strains A, B, F, G, and I have absorbed all the agglutinins present in serum H. Similarly, strains A, B, F, G, and H have absorbed all the agglutinins present in serum I. Thus, strains A, B, F, G, H, and I are serologically identical. If the source of these strains is recollected it will be seen that the organisms recovered from the throat of Nurse C are identical with those present in the blood of both patients and in the vagina of one of them, Mrs. Y. The results, therefore, of these experiments show that Nurse C was the carrier responsible for the infection of both patients.

Summary

1. Cases of puerperal pyrexia have been studied with a view to determining the source of infection.

2. Bacteriological examination of the secretions of the patients and the throats of possible carriers has been made, several strains of haemolytic streptococci being recovered.

3. Possible sources of infection have been discussed, and evidence of the source of infection by means of agglutinin absorption tests has been deduced.

4. In both cases it has been shown that the infecting organism was carried in the throat of a midwife who attended both cases.

RECOVERY OF VISION AFTER TWENTY-SEVEN YEARS

BY

NORMAN FLEMING

OPHTHALMIC SURGEON, PRINCE OF WALES'S GENERAL HOSPITAL

It has recently been my good fortune to be able to operate successfully on a woman, aged 35, who had been suffering from double lamellar cataract (as illustrated in Fig. 3) of an opacity such that she had only been able to distinguish between light and dark since she was 8 years old. Such an opportunity must be of very rare occurrence, and, consequently, there is no routine procedure for such cases; in the circumstances I think that a few notes on my experience may be of some interest.

The patient was employed as a telephone operator, and

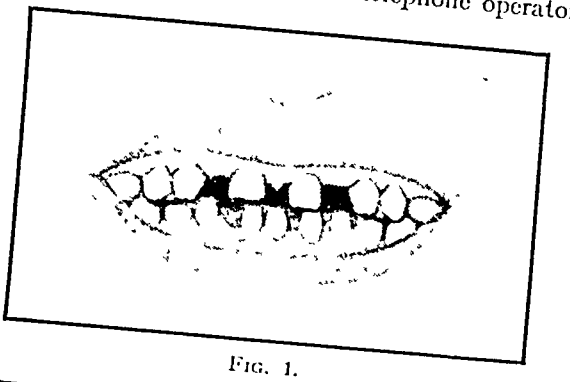

FIG. 1.

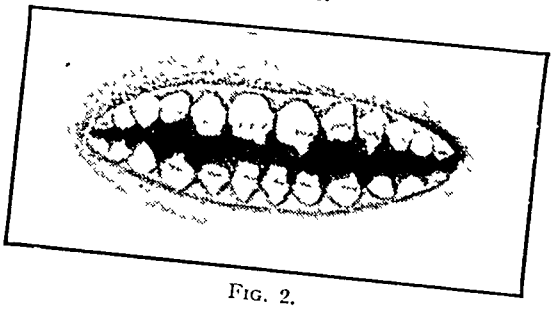

FIG. 2.

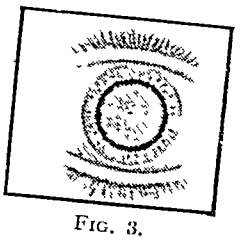

FIG. 3.

performed her duties quite satisfactorily, but her general health was not good; her complexion was bad, and she had little interest in life or in her personal appearance. When a very small child she had been able to see sufficiently well to learn her alphabet and elementary reading and writing, always holding her book very close to her eyes, as she was, in addition, highly myopic.

With regard to her present condition, her teeth illustrate well the defective enamel so frequently found in association with lamellar cataract; they are shown in the accompanying drawing (Fig. 1). Fig. 2 was drawn from a case of a boy, aged 14, on whom I operated for lamellar cataract some time ago; it clearly demonstrates the exposed dentine, affecting, as it almost invariably does, the central and lateral incisors, the canines, and first molars of the permanent dentition in upper and lower jaws; this is found to be worn away in the adult.

The presence of about 10 dioptres of myopia, as measured around the limit of the cataract with a dilated pupil, made me fear the possibility of a detached retina if any operation was performed involving a large opening in the eyeball. I decided to operate by needling only, to proceed by small stages, and to open the eye only in case of urgent need. On each occasion I used a Ziegler knife—one only—and wore a binocular loupe to observe the detail of the operation. On the first occasion I made one long cut only; on the second, two crescentic cuts, joining at each end; this was done to ensure the escape of the contained portion of lens matter and, at the same time, to limit the total amount of lens matter which could escape at one time and so obviate glaucoma. The technique proved to be most satisfactory.

On the day following the second operation I applied two leeches to control the small rise in tension which was inevitable; in this way all trouble from increased tension was avoided. Following the second operation three further needlings were performed on the right eye and four on the left; on each occasion the loupe was worn and the procedure adapted to the condition found.

The result was as follows:

$$\text{Right with } \frac{+4.00 \text{ DS}}{+1.00 \text{ DC Axis } 85^\circ} = \frac{6}{6} \text{ partly.}$$

$$\text{Left with } \frac{+4.00 \text{ DS}}{+1.50 \text{ DC Axis } 90^\circ} = \frac{6}{6} \text{ partly.}$$

With + 3.50 DS added each eye = J 1.

I consider that the failure to read 6/6 fully is due to imperfect development of macular function, as there is no medial obstruction or fundus disease.

Since the patient has been able to see, my efforts to improve her general health have met with remarkable success; she now has a good complexion, has energy and interest in life, and the natural pleasure of being able to choose her own clothes and attend to her own personal appearance has transformed her whole mental outlook. She has learned to write, has become a shorthand-typist, and hopes before long to leave her switchboard for another post, to which she looks forward with much interest.

The illustrations are from drawings prepared by Theodore Hamblin, Ltd., opticians, Wigmore Street.

ACUTE HAEMORRHAGIC PANCREATITIS

REPORT OF FOUR CASES

BY

J. W. GEARY GRANT, F.R.C.S.

CONSULTING SURGEON, CARDIFF ROYAL INFIRMARY

Although acute pancreatitis is perhaps not to be considered as one of the very rare causes of the acute abdomen, in general hospital statistics it appears to be infrequent. The occurrence of four cases in one year in the practice of a single surgeon, and the fact that they were all extremely typical of this condition, may justify recording them. The first two of these cases were verified at operation; the second two, unfortunately, were fatal, without operation, and in neither was a necropsy permitted. The symptoms in these latter cases were, however, so characteristic as hardly to admit of doubt. The first patient was a girl, aged 17 years, who was operated on and died, chiefly, I believe, because the tube draining her gall-bladder came out and allowed the escape of stones and bile into the abdomen, in this manner adding the factor of infection to what was, in my opinion, an aseptic inflammation of the pancreas. The second patient recovered. She was a woman, aged 50, who was also operated on in the same manner, and presented at operation much the same appearances. In both these patients the gall-bladder, while showing no definite signs of inflammation, contained numbers of very small cholesterol calculi, the type which, according to the theory of Opie and Archibald, readily lodge at the bile papilla, leaving the opening of the duct of Wirsung patent behind it, and so permitting the regurgitation of bile into the pancreas.

CASE I

Miss Charlotte P., aged 17 years, was a shop assistant. Four days prior to admission she had a sudden attack of severe epigastric pain, accompanied by persistent vomiting and constipation. The patient was sent in as a case of acute intestinal obstruction. On admission, she was obviously extremely ill, complaining of agonizing pain in the epigastrium. There was tenderness below the right costal margin and in the epigastrium, and rigidity over the upper abdomen. Tenderness was also present in the left costo-vertebral angle. Her face was flushed. Temperature 100°, pulse 126, respiration 24.

On November 13th, 1930, the abdomen was opened by a right upper paramedian incision, and a quantity of blood-stained fluid escaped. Extensive fat necrosis was scattered all over the omenta. The pancreas, which was exposed by tearing through the gastro-colic omentum, was found to be swollen and to resemble a piece of raw beef-steak. The gall-bladder was moderately distended, and contained a quantity of small round yellow cholesterol stones about the size of a hemp seed. The operation was rapidly concluded by fixing a tube in the gall-bladder with a purse-string suture. No attempt was made to remove all the stones, and a tube was passed down to the pancreas after scratching through the peritoneum over it. The abdomen was closed with through-and-through silkworm-gut sutures.

Blood sugar at this time was 0.2, the diastatic index of urine being 40. For a week the patient made great improvement and appeared to be on the road to recovery. On November 21st the tube draining the gall-bladder either came out of itself or was pulled out, and from that time she went downhill. On November 29th she was seized with agonizing abdominal pain. The abdomen was then reopened, and it was found that the bile and small gall-stones had leaked freely into the abdomen. The fat necrosis present at the original operation had disappeared. The pancreas was exposed with some difficulty, and was found to be surrounded by a quantity of blood stained fluid. The diastatic index of this fluid was 500. Ten days later the patient died, four weeks after the first operation.

Commentary

In my opinion the sequence of events was as follows. A small stone lodged at the papilla and bile was injected up the pancreatic duct, setting up an aseptic inflammation. With drainage of the pancreas and relief of pressure in the common duct by draining the gall-bladder no further bile reached the pancreas. All her symptoms were relieved, and recovery would probably have ensued, but when the tube came out of the gall-bladder, with the resultant escape of bile into the peritoneum and abdominal wound, an aseptic process in the pancreas became converted into a septic one, with a fatal result.

CASE II

Mrs. Mary J., aged 50 years, a housewife. For years the patient had suffered from attacks of epigastric pain radiating to the back, accompanied by nausea and flatulence. There was no jaundice at any time. Two days before admission to the Cardiff Royal Infirmary she had a severe attack of epigastric pain. The day after admission (August 19th, 1930), I was asked to see her by the house-surgeon, Mr. Morgan, as he thought she was a case of acute pancreatitis. Her face was cyanosed, especially round the lips. She was very dyspnoeic, speaking in gasps and with acute pain. Temperature 98°, pulse 100, respiration 40. The abdomen was distended and rigid. There was acute tenderness in the epigastric and umbilical regions, and at the left costo-vertebral angle.

The abdomen was opened by a right upper paramedian incision on August 20th, when a quantity of blood-stained fluid escaped. Numerous patches of fat necrosis were scattered over the omenta. The gall-bladder, containing a quantity of very small yellow stones, was opened and drained. The pancreas, exposed through the gastro-colic omentum, was swollen and red, and a tube was placed in contact with it. The patient steadily improved from the time of the operation, and was discharged on October 13th free from symptoms.

CASE III

S. E., aged 46 years, was a police constable. On June 20th, 1930, he was seen by me in consultation with Dr. Anderson of Penygraig, who diagnosed an attack of gall-stone colic, the symptoms being severe pain in the epigastrium passing round to the right scapular region, with vomiting. The attack had come on the previous night. When I saw him it appeared to be passing off, and the patient, who was afraid of operation, was endeavouring to make light of it. He was extremely fat, and it was very difficult to make anything out by examining the abdomen, except that there was tenderness in the gall-bladder region; but the history appeared pretty definitely to indicate biliary colic, and I had him admitted to my ward at the Royal Infirmary the following day. He had had a similar attack a week previously. The abdominal symptoms were now less in evidence, and as he was found to have some consolidation at the base of the right lung and was a very unfavourable subject for operation, he was transferred to Professor Kennedy's ward in the Medical Unit. The note states that there was then "tenderness in the right hypochondrium, and the right upper rectus was slightly rigid," and that there was "dullness, fine rales, and pleuritic rub in right axillary region and behind." I did not see the patient again, but was told by Professor Kennedy that the following day he was slightly cyanosed, and this condition became more marked the day after. The pulse varied from 112 to 136. Blood sugar, 400 mg. per cent. On June 25th, 1930, he was seized with severe abdominal pain, and was breathless and drowsy. He then became extremely cyanosed, and died the same day. A post-mortem examination was refused.

Commentary

Although not verified by operation or post mortem there seems little doubt that this was a case of acute pancreatitis; with this opinion Professor Kennedy is in agreement. Two attacks of biliary colic, a remission followed by sudden agonizing abdominal pain and rigidity, rapid pulse, marked cyanosis, and the presence of a very high blood sugar, would seem conclusive evidence. The patient was extremely fat and an alcoholic, and operation would probably have been unsuccessful, especially in view of commencing pneumonia.

CASE IV

With the view I hold of etiology of acute pancreatitis, this case is of particular interest to me. Mrs. P., a housewife, aged 34, was a patient of Dr. Nelson of Treherbert, who was called in by a midwife to a case of prolonged labour. Dr. Nelson found no evidence of pregnancy, and diagnosed intestinal obstruction. The patient was suffering from pains resembling those of parturition, the lower abdomen was distended, and there was obstinate constipation and occasional vomiting. This condition had continued for a fortnight. The patient was then sent into the Treherbert Hospital, where, on July 2nd, 1930, I opened the abdomen under general anæsthesia by a lower median incision. I found that she had had a subtotal hysterectomy, and that a loop of small intestine had become fixed to the cervical stump and was acutely kinked. It was separated, and the raw areas on the intestine and in the pelvis were peritonized. I happened to pass my hand to the upper abdomen and felt the gall-bladder, which was of normal size and consistency, but contained a quantity of small gall-stones, and I remarked then that these were just the sort of stones which might cause acute pancreatitis. As it was impossible to deal with the gall-bladder through a lower abdominal incision, and since her condition did not warrant doing anything further at the time, the abdomen was closed.

Three days later, July 5th, the patient was seized with acute abdominal pain, there was some distension, and she vomited a dark brown fluid. On July 7th she had severe pain in the back, and diarrhœa. On the following day she became cyanosed. Pulse 120, temperature subnormal. Vomiting of brown fluid and diarrhœa continued. On July 9th I was asked to see her, although I was told her condition was desperate. What struck one at once was her appearance. With all the symptoms of collapse she had a bright pink flush on her cheeks. Her pulse was 130, temperature 97°. There was acute tenderness at the pancreatic point above the umbilicus and in the left costo-vertebral angle. The diagnosis of acute pancreatitis appeared evident, but no persuasion would induce

her to let me operate again. The next day she became wildly delirious and was in agonizing pain, still passing dark brown fluid per rectum. She died that night. I feel convinced that after the gall-bladder had been handled a small stone worked its way down the cystic duct and lodged at the ampulla, causing regurgitation up the duct of Wirsung.

Commentary

Although the diagnosis, unfortunately, was confirmed neither by operation nor by post-mortem, the symptoms were so typical as not to admit of doubt. As to the cause the theory of infection seems untenable. No focus of infection was present in the abdomen, the gall-bladder showed no signs of active inflammation, and, at the operation for the relief of obstruction, the bowel was not opened, the operation resolving itself into the separation of an adhesion.

REMARKS

In three of these cases gall-stones were present, all of very small size, such as might block the opening of the common bile duct without at the same time blocking the opening of the duct of Wirsung.

In the *British Medical Journal*,[3] I published a series of twelve cases of acute necrosis of the pancreas, six of these being my own. In ten of these, gall-stones were present in the gall-bladder; in several it is noted that the stones were small. In one case with large stones in the gall-bladder, a small stone was found impacted at the ampulla of Vater. While not for a moment suggesting that all cases of acute pancreatitis are due to the impaction of a stone at the ampulla, I think there is no doubt that in many, if not most, of the acute fulminating cases the cause is the retrojection of bile or duodenal contents into one or other of the pancreatic ducts. In the early stages of the condition the evidence of infection is very slight in many cases. Graham, who at one time was an adherent of the theory of the lymphatic origin of pancreatitis, seems now to have changed his view, and in his recent work on the gall-bladder[1] quotes the investigations of Kodama[2] on the dog. Kodama found that dye injected into the subserosa of the gall-bladder passed in the lymphatic vessels over the pancreas to a gland at the commencement of the portal vein, and did not enter the substance of the pancreas; nor does it appear probable that infection is likely to pass against the direction of the lymph flow. The argument against the views of Maugeret, Deaver, and others has been very fully and clearly discussed by Fiske Jones,[4] and I need not recapitulate it here. It should, I think, carry conviction to those who are not irretrievably wedded to the elusive haemolytic streptococcus. He also points out, what one notes in Graham's work, that it is very difficult to make out whether the upholders of this theory are referring to the above condition or to the chronic interstitial pancreatitis which may conceivably have a lymphatic origin. I quote his remark on this subject: "It is impossible to read the articles of Deaver and others who accept Maugeret's theory as to the cause of pancreatitis, and those of Archibald and others who believe in Opie's theory, without feeling that they are discussing two different diseases."[4]

The question is of more than academic interest, for correct treatment depends, to a large extent, on the view we take of the causation.

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

EFFECT OF INTRAVENOUS MAGNESIUM SULPHATE ON THE BLOOD PRESSURE IN URAEMIA

The treatment of uraemia in acute glomerular nephritis by the intravenous injection of magnesium sulphate was originally described by Blackfan and Hamilton (*Boston Med. Surg. Journ.*, October, 1928). They reported eleven cases of children in whom the treatment was used. Of these, eight recovered, and three, in whom it was not used until the terminal stages, died. Blackfan and Hamilton used the treatment in the acute glomerular type of nephritis, characterized clinically by the acute onset, the slight degree of oedema, and a rise in the blood pressure, together with haematuria and albuminuria. This glomerular type shows a marked tendency to progress to uraemia. They found that the degree of oedema and haematuria, and even of oliguria, was of no great significance, provided that the systolic blood pressure remained below 130 mm. But if the blood pressure commenced to rise above 130, with, as often occurred, vomiting, headaches, and visual disturbances, they regarded magnesium sulphate treatment as indicated. Their technique was the slow intravenous infusion of 1 per cent. magnesium sulphate (2 grams of the crystalline salt, $MgSO_4 + 7H_2O$, in 100 c.cm. of distilled water).

CASE HISTORY

A boy, aged 9, was admitted on February 22nd, 1931, with a history of vomiting and sore throat of three days' duration. On examination he was found to have the red throat, tongue, and enlarged glands of a typical thirdday case of scarlet fever, with a temperature of 99° F. and a pulse rate of 112. His urine was then free from albumin. The disease followed a normal course until March 16th (twelfth fifth day of disease), when the routine urinary examination showed that albumin was present. The next day red blood corpuscles, and granular and epithelial casts, were seen microscopically, and the patient's face was noticed to be pale and puffy. A diagnosis of acute glomerular nephritis was made. The bowels were freely opened by the regular administration of jalap, pil. colocynth, and sodium sulphate. However, on March 19th (fourth day of the nephritis) he had six convulsions, lasting from three to eight minutes each, spread over an hour and a half, with complete unconsciousness between. He was then treated by venesection, and chloral and potassium bromide per rectum. Two hours later the patient was still semi-conscious, with a blood pressure of 148/132; 150 c.cm. of 1 per cent. magnesium sulphate was then sterilized and given intravenously by the gravity method. The following systolic blood-pressure readings from the fever chart kept show the effect (the diastolic was found to follow the systolic): after one hour, 148; three hours, 146; six hours, 122; eight hours, 128. By the next morning the systolic blood pressure was found to be 150, and intravenous magnesium sulphate was repeated. The effect on the blood pressure was: after one hour, 144; three hours, 144; six hours, 122; eight hours, 128. The following morning (sixth day of nephritis) the reading was 108, and in the evening 126. After that, except for one reading of 134 on the seventh day of the nephritis, it settled at 120, gradually falling to 112. From the onset of the nephritis the urinary output varied from 8 to 19 ounces until March 24th, when 38 ounces were passed, after eight days of partial suppression. The magnesium sulphate did not affect the quantity of urine. Red blood corpuscles disappeared from the urine on the fourteenth day of the nephritis, and albumin on the fifteenth day. The patient appeared to have suffered no permanent damage to the kidneys, having no recurrence of albuminuria on leaving his bed, and being perfectly well on discharge, ten weeks from admission.

SUMMARY

The systolic blood-pressure readings show that after the first injection there was a fall of 26 mm., and after the second a fall of 28 mm. In both cases the maximum fall was recorded after six hours. These falls in the blood pressure were accompanied by a marked clinical improvement, the patient becoming much less drowsy. The mode of action of the magnesium sulphate is difficult to determine. The quantity of magnesium used is insufficient for the radicle to exercise its sedative action to any appreciable degree. The explanation advanced by Blackfan and Hamilton is that the rise in blood pressure and the uraemia symptoms are due to oedema of the brain. They suggest that this oedema of the brain is reduced by a change in the osmotic relationship between the blood and the tissues of the brain, such as is supposed to occur when salt solution is injected. This change, they suggest, may be due to an increase in the total electrolyte content of the blood. The series described by Blackfan and Hamilton contained no cases of scarlatinal origin; hence it is interesting to note that this case also responded to the treatment. In view of the frequency with which uraemia causes a fatal termination in scarlatinal nephritis, this treatment would seem to offer a useful method of warding off a fatal uraemia until resolution of the nephritis occurs.

I wish to thank Dr. W. T. Benson for permission to publish this case.

C. B. WATSON, M.B., L.R.C.P.Ed.

City Hospital for Infectious Diseases, Edinburgh.

PELVIMETRY BY *X* RAYS

No originality is claimed in arriving at measurements of the true conjugate and transverse diameters of the bony pelvis, but a simple account of the following method may interest those who have not yet tried it.

Antero-posterior and lateral films are taken with centring respectively one and a half inches above the os pubis and just before the great trochanter. Using 20 mA. and doubly screened films, exposures of four and seven seconds respectively are made at 80 to 100 kV. on the Potter-Bucky. It is then necessary to measure the thickness of the patient from pubes to table (a), and her extreme width across the trochanters (b). Let the focus-film distance be 28 inches (c). On the antero-posterior film the transverse diameter is measured (d), and on the lateral film the distance from the sacral promontory to the back of the os pubis (e). The calculation is as follows:

$$\frac{d \times (c - \frac{2}{3}a)}{c} = \text{true transverse diameter}$$

$$\frac{e \times (c - \frac{1}{2}b)}{c} = \text{true conjugate diameter}$$

An actual case may be cited to dispel any doubts as to the ease and simplicity of the method.

Thickness of patient	8 inches	(a)
Width of patient	14 "	(b)
Focus-film distance	28 "	(c)
Transverse diameter measured on film	6½ "	(d)
Conjugate diameter measured on film	5½ "	(e)

$$\frac{6\frac{1}{2} \times (28 - \frac{2}{3} \text{ of } 8)}{28} = \frac{6\frac{1}{2} \times 22}{28} = 5.26 \text{ true transverse}$$

$$\frac{5\frac{1}{2} \times (28 - \frac{1}{2} \text{ of } 14)}{28} = \frac{5\frac{1}{2} \times 21}{28} = 3.94 \text{ true conjugate}$$

Or approximately 5½ and 4 inches.

Tests on the skeleton show an accuracy to within one-twelfth of an inch.

British Medical Association

CLINICAL AND SCIENTIFIC PROCEEDINGS

FIFE BRANCH

INSANITIES ASSOCIATED WITH CHILD-BEARING

At the first sessional clinical meeting of the Fife Branch, held at the Fife and Kinross District Asylum, on November 12th, with Dr. JAMES ORR (St. Andrews), president of the Branch, in the chair, Dr. WILLIAM BOYD, medical superintendent of that institution, delivered an address on the insanities associated with child-bearing.

Dr. Boyd said that insanity as a whole was much more common in the male than in the female. Between the ages of 20 and 35, however, it was more frequent in the female, owing to the insanities attributable to reproduction, which accounted for 8 to 10 per cent. of all types of insanity met with in the female sex. Four groups of child-bearing insanities could be defined—namely: the insanity of pregnancy (20 per cent.); lactational insanity (30 per cent.); and the insanities of parturition and the puerperium, which together amounted to 50 per cent. No form was peculiar to the reproductive period, but a definite group could be recognized, because the clinical picture was so clearly coloured by the reproductive process; in the majority of cases there was a toxic basis. In addition to child-bearing, certain other factors were present to determine the breakdown: psychopathic or neuropathic heredity; age; exhaustion (including haemorrhage, frequent pregnancies, and instrumentation); change in blood pressure; illegitimacy; emotional stress; auto-intoxication; septic conditions; and endocrine disturbances.

Insanity of Pregnancy

Here the early symptoms were an accentuation of the "longings" of neurotic women, with irritability, excitability, and absurd and extravagant tastes. Sleeplessness was an important factor, and the patient became restless and over-anxious. Morning sickness was excessive, and delusions were present. She refused food, expressed dislike of her husband, and became apathetic and careless, neglecting the household duties. The physical signs were those of melancholia, an important point being constipation; since these patients did not complain of pain, a look out must be kept for retention of urine, oedema of the legs, and the development of varicose veins. The course of the disorder depended on the time of onset. If it began before the fourth month, recovery was usual at the time of quickening. If it appeared after the fourth month, the insanity continued for several months after birth. The prognosis was good in the early months, but less favourable in the later months, the insanity persisting in one-third of the cases. The treatment was that for melancholia, and included rest, dieting, and measures directed to the correction of constipation and insomnia. Refusal of food called for forcible feeding, and any physical symptoms should be dealt with; premature delivery was not indicated. The possibility of suicide was an important consideration, and all modes of suicide must be anticipated and prevented.

Insanity of Parturition

This appeared as a state of delirium or acute mania; hallucinations were present. The treatment was delivery without delay and maintenance of the blood pressure. In puerperal insanity the patient was excited, noisy, and

restless, singing and shouting. She refused food; insomnia was constant, and hatred was displayed for the husband and nurse. Hallucinations of sight and hearing developed; remissions were not uncommon, but the excitement always returned. The physical signs were those of an infective condition, and complications were likely to occur, such as breast abscess, pyelitis, and cardiac failure. The course taken by this form of insanity depended on the severity of the attack. If the health improved, the excitement subsided in a few weeks, recovery ensuing in a month or two, after a state of apathy. There was some danger of the occurrence of prolonged subsequent weakmindedness. As regards diagnosis, the possibility of puerperal fever had to be remembered; it would be indicated by a high temperature, rigors, and suppression of the lochia. The prognosis depended on the time of onset; the earlier the onset the better would be the prognosis. In delirious forms the outlook was bad, and the majority of patients died. Treatment comprised attention to the symptoms and guarding against complications. Sedative drugs were required to allay the excitement, and drugs to raise the blood pressure were often beneficial. Puerperal insanity had a medico-legal interest; insane mothers might be delivered unconsciously and injure their children accidentally.

Lactational Insanity

This usually commenced during the third or fourth month after delivery. The patient became irritable, restless, and sleepless, and developed ideas of persecution, directed towards the husband and child. The majority of cases were of the subacute melancholic type, and ideas of unworthiness were expressed. Suicide and infanticide were common. In cases of exhaustion the patients were confused and hallucinated. The physical signs were those of melancholia, and constipation was constant. The patients were anaemic and debilitated, and loss of appetite was frequent. The disorder usually persisted for some months, but the prognosis was good in the depressed cases, though the disorder ran a long course. In acute delirious forms the prognosis was bad, the patients dying from broncho-pneumonia or acute broncho-pneumonic tuberculosis; improvement often occurred when menstruation returned. The treatment was that of melancholia: rest was essential, and breast-feeding must cease. Attention should be given to the insomnia, diet, and bowels. General tonics should be administered in the form of the scale preparations of iron, and guard should be maintained against suicide and infanticide. Glandular therapy was worth trial in the exhausted types. The toxaemia should be attacked by ensuring regular habits of feeding, defaecation, and micturition. The diet should contain an excess of fat and fruit juice. The bowels required constant attention, the best treatment being a course of calomel, with daily colonic lavage.

Although these were the common types of disorder encountered during child-bearing, other mental disorders might appear, precipitated by the stress so incurred. The chief of these were paranoia, dementia praecox, and general paralysis of the insane. In these child-bearing insanities the question of certification and admission to an asylum might require consideration, but this really depended on the home circumstances. In the insanity of pregnancy an attempt might well be made to treat the patient at home in view of the possibility of a stigma being attached to the child. The patient would, however, require to be dealt with by a nurse trained in mental disorders. The risk of suicide was always present, and in the case of the poorer patients suffering from these insanities there were no facilities other than those offered by the asylum.

Reports of Societies

OBSTETRICS AT THE ROTUNDA

At a meeting of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine on November 20th, with the president, Mr. VICTOR BONNEY, in the chair, Dr. BETHEL SOLOMONS read a paper on methods of obstetric diagnosis and treatment at the Rotunda Hospital in 1909 compared with 1929.

Dr. Solomons stated that he had now been Master of the Rotunda since 1926, and it was therefore possible to review dispassionately the new ideas, to compare them with the old, and to endeavour to sum up the best of each. During that time he had had the opportunity of studying the results of over 20,000 labours. In 1909 there were two labour wards with stone floors, which were used on alternate weeks. These wards were small and inconvenient for teaching, but there was an undoubted value in being able to give each theatre a rest for thorough cleaning. The bigger theatre now in existence was of very great value from the teaching point of view. Dr. Solomons went on to discuss certain technical points in midwifery. He first dealt with fixation of the foetal head in primigravidae. He found that in 19.5 per cent. of all such cases the head was not fixed in the pelvis at the time labour started, and of these, 75 per cent. delivered themselves spontaneously, and resulted in a normal live child. In 10 per cent. delivery was effected by forceps, and in the remaining 15 per cent. more serious operative treatment was necessary, including lower segment Caesarean section. He spoke enthusiastically of this method, and considered it superior to the higher incision. He next discussed the question of pelvimetry and disproportion. In 1909 he relied almost entirely on the Skutsch pelvimeter, and he still thought that this instrument was of considerable value; on the other hand, if time and place permitted, radiographic pelvimetry gave the best results. During the twenty years under discussion the number of cases of disproportion had increased enormously, and he found it rather difficult to give any satisfactory explanation. It might be due to the present generation having been affected by malnutrition and other factors during the great war.

As regards the third stage of labour he had come to the conclusion that more harm than good was done by controlling the fundus. The danger lay in the assistant being over-anxious, and liable to produce hour-glass contraction and other abnormalities, by constant manipulation. Next he referred to the toxaemias of pregnancy and accidental haemorrhage. The incidence of accidental haemorrhage had increased from six in 1909 to forty-one in 1929, and he was at a loss to understand it. He had entirely given up plugging the vagina for this serious complication, and relied on puncture of the membranes, repeated doses of pituitary extract, and treatment of collapse by saline when necessary. On the question of inducing labour, he professed himself a convert to the method of puncture of the membranes, and was in entire agreement with other authors, including Guttmacher, Douglas, Jackson, and FitzGibbon. In the treatment of inertia watchful expectancy was necessary, and he taught the complete abolition of oxytocic drugs such as pituitrin. In his opinion the pendulum had swung too far in the avoidance of forceps, but the use of Kielland's instrument was dangerous, and suggested meddlesome midwifery. When the head was low the obstetrician should use the instrument to which he was accustomed. Referring to the lying-in period, he stressed the importance of patients sitting up in order to obtain the best drainage of the pelvis. Finally, on the question of the teaching of students, he was of the op-

that the number of cases actually delivered by the student was of less importance than the time spent in a large maternity hospital. At least two months should be the minimum.

The PRESIDENT congratulated Dr. Bethel Solomons on his very excellent and helpful paper. Mr. ALECK BOURNE could not agree with the entire neglect of the fundus uteri during the third stage of labour, inasmuch as it was not possible without a hand on the fundus to be aware of the collection of a concealed post-partum haemorrhage. By control of the fundus he did not mean violent kneading, but a gentle grasp which would prevent the fundus filling up with blood without the doctor's knowledge.

Mr. L. CARNAC RIVETT said his instructions were to make this discussion as acrimonious as permissible within the walls of the society. Dr. Solomons, however, had cut the ground from under his feet, as he found he was in complete agreement with practically everything in the paper. He, Mr. Rivett, was not going to let a trifle like that impede him. He entirely agreed with the Master in regard to pelvimetry, but he did not think that *x*-ray pelvimetry was yet established. He could not understand the difficulty in teaching the use of the head as a pelvimeter. In his opinion the fit of the head could be diagnosed in most cases by pressing the head into the brim with the palm of the hand, and not with the tips of the fingers. In a few exceptional cases the Munro Kerr method was necessary, and in that case an anaesthetic was also necessary. Did the Master really mean that he taught leaving the uterus entirely alone during the third stage of labour, and that he had never seen any ill effects from this? In regard to anaesthetics, hyoscine was not only dangerous to the infant, but it pushed the full amnesia, occasionally producing mania in the mother. He was sorry to hear the Master say that chloroform was dangerous, and was not used at the Rotunda. Was the Master stating that this drug was so dangerous that he would never use it, without having tried? Mr. Rivett was very much in agreement with the remarks on teaching, except that he did not consider the number of cases was anything like sufficient. Every student ought to deliver at least thirty cases, and have at least ten obstetric operations, including forceps, version, and even embryotomy.

Mr. W. GILLIATT was in complete agreement with most of the things that the Master of the Rotunda had described as his normal practice, and particularly with the abolition of chloroform in maternity hospitals and in maternity departments. He could not, however, share his feeling of safety at leaving the fundus uteri without a hand upon it. He considered that there were two other notable changes in practice in the last twenty years which were beneficial: first, the invention and use of Willett's forceps; and, secondly, blood transfusion, which in his opinion should be used in every case of ante- or post-partum haemorrhage where the haemoglobin estimation was less than 55 per cent. forty-eight hours after the termination of labour.

Dr. W. H. F. OAKLEY said that during the thirty years he had been actively engaged in midwifery he had come to rely less and less on instruments of any kind, and more on the use of the two hands where intervention was absolutely necessary. Thus in the 10,000 cases he had recently reported, the forceps rate was only 2.9 per cent., and only one Caesarean section was performed. He thought that careful guarding without irritation of the uterus was necessary, and was confirmed in this belief by reading the reports of a hospital on the Continent, where, after delivery, the abdomen was covered by a towel and the uterus neither palpated nor observed. Out of 2,623 cases delivered there were 244 cases of severe post-partum haemorrhage and 240 of retained membranes, numbers far in excess of those where the English method obtained. In most cases it would be found best to choose one way out of many good ways of treating a condition, and to stick to it. The whole outlook on midwifery had altered in the last twenty years, owing to the introduction of ante-natal care, the provision of a large number of trained midwives, and the benefit derived under national health insurance, which enabled a prospective mother to leave work during the last few weeks of pregnancy, and to have a longer rest during the puerperium. The preventive outlook had made an enormous difference, and he was sure that we should not get the best results until every mother had close personal attention during the whole of pregnancy, parturition, and puerperium.

Lady BARRETT thought that pituitrin had a use in medicine, but required the greatest care in use toward the end of labour, when the uterine muscles might be nearly exhausted. With regard to the use of forceps at the end of labour to save the mother pain, she felt that anaesthesia, which relieved the suffering, and at the same time allowed labour to be completed more slowly and normally, was better treatment.

Dr. BETHEL SOLOMONS, in reply, said that he definitely did not believe in control of the fundus, nor did he believe that post-partum haemorrhage was caused by non-control. As he had seen severe accidents and even fatalities following pituitrin in labour, he was inclined to avoid it, even though it might be useful in infinitesimal doses to assist in starting labour, and possibly in the very early stages. The main fact was that it required an extensive experience to settle on the type suitable for its use. Fibrillary contraction of the uterus had already been noted from the Rotunda. As chloroform was killing women in most maternity hospitals, he had adopted ether as an anaesthetic at the Rotunda. Gas and oxygen might be more suitable, but they were very expensive. He disagreed entirely with the use of the curette in the puerperium. It should never be used, and no teacher had any right to allow it to creep into his lectures. He taught the use of Willett's forceps at the Rotunda, but they had very little use. Donors of blood were not always available for the general practitioner.

X RAYS IN UTERINE DISEASE

A paper was also read by Dr. LOUISA MARTINDALE on recent advances in deep *x*-ray therapy in non-malignant and malignant uterine disease. She said that there were two big groups of cases in which *x* rays were of value—non-malignant and malignant. Considerable advances had been made in the technique, particularly in the treatment of glandular hyperplasia of the endometrium, fibromyomata of the uterus, and adenomyomata. She traced the advances from 1902, when W. J. Morton treated his first case of fibromyomata. From 1913 to 1920 the small-field cross-fire method was used, and the years 1920 to 1927 showed the development of high-powered *x*-ray apparatus, eventuating in the Stabilivolt installation. She enumerated the now well-known contraindications which definitely limited the number of cases it was safe to treat by deep *x* rays. In her own series of 500 cases she had treated 260 by surgical operation, 224 by deep *x*-ray therapy, and 16 by radium. Regarding the possibility of regulating the menstrual loss by irradiation of one ovary only, she concluded that this method is not certain enough to be advocated. Another method was to give a 28 per cent. of unit skin dose to each ovary. The author had herself used it in rare cases of menorrhagia in younger women, and in three of such cases the temporary amenorrhoea was followed a few years later by healthy pregnancy and childbirth. In discussing *x* rays for malignant disease, Dr. Martindale described the methods used at various clinics. She showed figures indicating

that there was a considerable improvement in the five-year survival rate with the more modern methods. Summarizing the actual recent advances in deep *x*-ray therapy in uterine disease, she said that the results in the newer technique in the treatment of small interstitial fibromyomata and climacteric haemorrhages were excellent, succeeding in curing 98 per cent. of cases, and, further, that the necessary treatment could now be carried out in a much shorter time than formerly—namely, in from thirty-five to ninety minutes, depending on the type of case. The improvement in results was due not only to the newer types of *x*-ray installations, but also to the more general acknowledgement on the part of gynaecologists of the necessity for better care of the patient both before and after radiotherapeutic measures.

The PRESIDENT objected strongly to the use of *x* rays in the treatment of fibroids. There were exceptional cases in which their use was justified, but to destroy as a routine healthy ovaries for the sake of a diseased uterus was an altogether wrong principle. Fibroids subjected to *x*-ray treatment often shrank, but never entirely disappeared, and he had had on many occasions to operate on elderly women because fibroids thus shrunken were giving rise to trouble. The ideal treatment of fibroids was myomectomy, and the technique of that operation was now so much improved that very few cases were outside its scope.

ACUTE HEAD INJURIES

At a joint meeting of the Sections of Neurology and Surgery of the Royal Society of Medicine on December 2nd, with Mr. C. H. FAGGE in the chair, a discussion on the diagnosis and treatment of acute head injuries was opened by Dr. GEORGE RIDDOCH.

Cases of head injury, Dr. Riddoch said, were frequent, and appeared to be on the increase. Effective treatment in the early stages could do much to prevent sequelae. Concussion, the commonest result of head injury, had been defined as a widespread paralysis of the function of the brain. Concussed patients showed a tendency towards recovery. The onset of symptoms followed immediately on the injury, and might include loss of consciousness, dizziness, and sometimes confusion. In a mild case there was no change in pulse or temperature, and the patient might carry out whatever he was doing, even to the extent of playing out a game of football. Afterwards he might have no recollection of his actions following the injury, and his behaviour at the time usually gave the impression of imperfect conscious guidance. In a severe case, loss of consciousness was deep, the pupils might be fixed, the pulse rate slow, reflexes abolished, and the blood pressure low, indicating loss of function in the cerebrum and brain stem. If the bulbar centres were affected respiration suffered first, and might be suspended long enough for artificial respiration to be needed to tide the patient over the first shock. As recovery took place the heart began to beat more forcibly, the patient vomited, consciousness returned, he was restless, stupid, or irritable, and complained of headache. If recovery was delayed, if unconsciousness or a stuporous state persisted, if there was local paralysis, or blood in the cerebro-spinal fluid, brain injury must be suspected. Symptoms of severe concussion with fixed pupils and bulbar signs were almost always associated with contusions throughout the brain, in spite of the contrary opinion often expressed by pathologists. After the initial collapse, patients with cerebral contusion began to recover slowly; they were irritable or drowsy, complained of severe headache, vomited, and were sometimes delirious at night. This state might persist for days. Even when the more serious symptoms abated the headache often persisted, and might be accompanied by loss of attention and initiative, by irritability and sleeplessness. Headache might be associated with either an increase or a decrease of tension within the skull. Where it was due to hypertension it was severe, and aggravated by emotion, strong light, physical effort, or by lying down. The pressure of the cerebro-spinal fluid was found to be raised. Headache due to hypotension was associated with a low pressure of cerebro-spinal fluid, and was relieved by lying down. These patients were often relieved by tilting up the foot of the bed on blocks. Gross mental defect for longer than a few days was uncommon, though minor mental disturbances, such as loss of attention and initiative, were frequently found. Focal signs of cerebral contusion were sometimes absent. When present, they usually affected the pupils, the sense of smell or of hearing. Diplopia, squint, or defect of conjugate lateral movement of the eyes was sometimes found. Rarely, a Parkinsonian state followed head injury, and epileptiform fits had been known to develop months or even years afterwards.

Surgery had little place in the early treatment. Rest for a week or ten days was advisable after slight concussion. In severe concussion the patient must be treated for shock and kept at rest; strychnine was sometimes valuable at this time, and some clinicians recommended the use of pituitary. When the stage of reaction was over, lumbar puncture might be performed, and the pressure of the cerebro-spinal fluid measured. If it was high the patient should be propped up; if low the foot of the bed should be raised. To reduce intracranial pressure three methods were available. The first of these, lumbar puncture, was not without danger, and its use should be confined, he considered, to cases where there was much free blood in the cerebro-spinal fluid. The second method was to give hypertonic solutions intravenously, by mouth, or by the rectum. Glucose could be given intravenously, and magnesium sulphate by way of the alimentary tract. This was also a dangerous measure if pushed too far, but was valuable in some cases. Operative decompression, the third method, was not often necessary. To raise the intracranial pressure the patient should remain lying down, intravenous injections of hypotonic solutions being given. He did not favour the use of morphine to control restlessness; bromide and chloral were safer. The patient should remain at rest for three weeks after an injury with contusions, and convalescence should cover another three or four weeks.

Mr. GEOFFREY JEFFERSON said that in all cases of head injury serious enough to call for treatment in the early stages the state was probably due to contusion of the brain. Trotter regarded the symptoms of concussion as being due to an arrest of the cerebral circulation. Whatever the actual mechanism, it was likely that these patients who remained stuporous had suffered cerebral contusion. Contusion was usually taken to imply haemorrhage, and small haemorrhages were frequently found scattered in the brain substance in such cases, but they were not nearly so widespread as was generally supposed, being for the most part limited to the pole and to the vicinity of any laceration. Oedema was frequently found round the cells of the cortex, and the perivascular sheaths of the capillaries were often distended with red blood cells so closely packed that they could only have collected by rupture of the vessels. Perivascular oedema was also a common finding in the region of a haemorrhage. It was possible that these appearances were artefacts, but they were not seen in ordinary sections prepared in the same way. Possibly these collections of oedema might themselves injure the tissues into which they were forced. In the ventricles the fluid might be driven downwards towards the bulb. Animal experiments showed that this might cause death if it occurred rapidly.

but he had not seen it happen in man. Surgeons took the view that patients with head injuries who failed to recover consciousness were suffering from compression, but actually a number of them were not compressed at all. The pressure of the cerebro-spinal fluid might be low, and this explained why intravenous injections of hypertonic solutions were not invariably successful. The histological pictures of oedema were so striking that he considered the use of hypertonic solutions rational in most cases. But it would not produce improvement in patients with cerebral contusion, and it should not be used until the pressure of the cerebro-spinal fluid had been found to be high. Lumbar puncture was dangerous if used as an uncontrolled therapeutic measure. Haemorrhage from the middle meningeal artery was comparatively rare, but had received exaggerated attention in the textbooks. Venous bleeding with subdural haematoma was commoner in his experience than extradural haemorrhage, and acute subdural haemorrhage could cause death as rapidly as bleeding from the middle meningeal artery.

Dr. RITCHIE RUSSELL described the records of 200 cases of head injury investigated at the Royal Infirmary, Edinburgh. These had been grouped according to the length of loss of consciousness. In uncomplicated cases, he said, the steps in recovery were similar. The patients might be in a drowsy, talkative, or unreserved state, and would then, quite suddenly, realize that they were in strange surroundings. Retrograde amnesia was usually brief, seldom covering more than one or two minutes. The pupils might be affected, and the plantar response was often extensor, particularly in those patients who failed to recover. Rigidity was often a sign of subarachnoid haemorrhage; the red cell count in the cerebro-spinal fluid gave some indication of the extent of haemorrhage. There was a large group of stuporous patients in whom the pressure of the cerebro-spinal fluid was low, and another group of patients whose mental condition appeared to be normal, but in whom the pressure of the cerebro-spinal fluid was high. Those with a high red cell count in the fluid were often stuporous and no red cells could be found, as a rule, four or five days after the injury. The white cells shared in the fall of the cell count except in one case where purulent meningitis had developed. He did not consider that it was always desirable to attempt the reduction of intracranial pressure in the early stages, when a high tension might have a function in checking haemorrhage. The use of morphine appeared to be safe, provided the patient was allowed to recover between each dose.

Mr. J. P. Ross mentioned the difficulty of recognizing subdural haematoma where it was subacute rather than chronic. He described a case in a man of 40, who sustained a fracture of the left parietal. The symptoms were those of contusion, but on the twenty-third day his pupils became unequal for the first time, and he died within an hour. Post-mortem examination revealed a large subdural clot. A second case had a somewhat similar history, and Mr. Ross gave it as his opinion that where any patient diagnosed as suffering from contusion was not doing well, the cranium should be explored. He asked whether the presence of haemorrhage could be ruled out of consideration if the pressure of the cerebro-spinal fluid was low, and described a case in which conservative treatment had been successfully adopted on this assumption. He had also deliberately refrained from operating on four cases of depressed fracture of the skull, and had obtained good results. He asked whether the meeting considered that depressed fractures invariably required operation.

Mr. JULIAN TAYLOR described a case in which cerebral oedema had been demonstrated by the discovery of arachnoid blisters at operation. In dealing with subdural haemorrhage he reminded the meeting that the larger the lesion the more slowly it grew, and the more urgent was the need for operation. A mild bout of coma might be followed by a severe one in which the patient died, so that it was essential to make the diagnosis as early as possible, and to explore both sides for the haemorrhage. The brain would to some extent accommodate itself to the growth of the haematoma, but there was a point at which it would be suddenly overcome.

Mr. DONALD ARMOUR asked what was the basis of photophobia occurring as an isolated symptom following a head injury, and described cases in which severe photophobia had occurred, apparently without other symptoms.

Dr. C. P. SYMONDS proposed the adoption of "traumatic stupor" and "traumatic delirium" in place of vaguer terms which had been used, such as "cerebral irritation." He considered that in head injuries the state seldom bore a resemblance to cerebral compression as found in patients with cerebral tumour or hydrocephalus, and that the symptoms were more likely to be due to injury to neural tissues. On the Continent recent observations made on patients dying from intercurrent disease within a few weeks of a head injury showed that there were changes present in the nerve cells and myelin. These might account better for the clinical picture than the compression theory. He agreed that morphine could safely be used in the manner described by Dr. Russell.

Dr. RUSSELL BRAIN said that Mr. Jefferson had explained clearly why hypertonic solutions were often valueless. They increased the osmotic pressure of the blood, and, consequently, not only reduced the flow of cerebro-spinal fluid, but increased its absorption; but, as Mr. Jefferson had shown, the perivascular sheaths of the capillaries were distended with fluid, so that absorption must be defective; and he doubted whether it was wise to add to the strain on the capillaries by trying to promote absorption through a damaged channel.

In reply to the chairman, who asked whether there were any clinical signs by which it was possible to recognize the type of case in which lumbar puncture might be harmful, Mr. Jefferson said that it was dangerous to draw off a quantity of cerebro-spinal fluid by lumbar puncture from a patient who was stuporous and cyanotic. He had found cases in which extradural haematoma was associated with a low pressure of cerebro-spinal fluid. He agreed that where subdural haematoma was suspected both sides should be explored.

Dr. RIDDOCH, in reply, said that the existence of photophobia as an isolated symptom was difficult to explain. Some symptoms of cerebral irritation might have been present in the cases described by Mr. Armour.

OBSTETRICS AND GYNAECOLOGY

At a meeting of the North of England Obstetrical and Gynaecological Society, held in Manchester, Professor CARLTON OLDFIELD (Leeds) described an unusual case of obstructed labour, due to retroflexion of the full-term gravid uterus.

The patient, who was a primigravida aged 25 was not examined ante-natally. She had no abnormal symptoms during pregnancy. The membranes ruptured twelve hours before the onset of labour pains. Her doctor was then called in and found the fundus 2 to 3 inches above the umbilicus, and, on vaginal examination, an arm presenting and a large mass in the hollow of the sacrum. The os was high up and could not be reached. The patient was admitted to a nursing home, and Mr. Oldfield opened the abdomen, intending to remove the tumour and deliver later *per vias naturales*. On inspection of the uterus it was noted that the bladder reflection lay a hand's breadth above the symphysis. The uterus on being lifted out of the abdomen tended to slip back. The tumour, having been raised from the pelvis, was

found to be uterine, possibly a fibroid. As the child lay obliquely its position was rectified, the arm being replaced by pressure upwards through the pouch of Douglas and the head placed over the brim of the pelvis. It was then decided to remove the tumour. A small incision was made with a view to enucleation, but on deepening this it was found that the placenta had been entered. The incision was therefore enlarged through normal thick uterine tissue and a Caesarean section performed. It was now evident that the incision was on the posterior wall of the uterus, extending from the insertion of the right tube obliquely down and to the left. Apart from a crack in the peritoneal surface of the posterior wall at the junction of the two segments no sign of adhesion or injury could be found. Mother and child both did well.

Professor DOUGAL (Manchester) described an unusual case of carcinoma of the cervix uteri.

The patient, aged 31, had been married five years, but had not been pregnant. The periods were regular, the loss normal, and there was no intermenstrual discharge. She was admitted to the Manchester Royal Infirmary as a case of pyrexia of unknown origin. There was a history of ill-health for four months, and a continuous temperature ranging from 100° to 103°, with night sweats. Repeated and varied physical and laboratory examinations having failed to reveal anything beyond a severe secondary anaemia, the the speaker was asked to see her. A tentative diagnosis of cystic disease of the cervix with infection was made after examination, and confirmed by further examination under an anaesthetic. Before anything could be done the patient died. At post-mortem the condition was found to be a cystic carcinoma lying to the left of the canal and displacing it to the right. Both iliac and lumbar glands were infected, and contained malignant deposits. Microscopically the tumour was found to be a very active squamous-celled (not, as one would have expected, columnar-celled) carcinoma. Though sufficiently advanced to produce metastases in the lumbar glands it had not yet broken through into the cervical or vaginal canal. The age and nulliparity of the patient, the absence of bleeding discharge and pain, were remarkable features of this case.

Mr. N. T. EDWARDS (Derby) showed a pear-shaped multilocular cystic tumour growing in the anterior part of the right labium minus. The cystic spaces were lined by cubical epithelium dipping down in places into the stroma and suggesting sweat glands. The patient, a multipara, had had the tumour as long as she could remember. It became swollen and painful at the menstrual periods. Mr. Edwards inclined to the view that it was an adenoma arising from a sweat gland.

Mr. S. B. HERD reported a case of rupture of the uterus during spontaneous delivery.

The patient, when a primigravida aged 35, two weeks post-mature, was delivered by classical Caesarean section after being in labour for forty-six hours. Convalescence was afebrile. Five years later she was again pregnant, and the pelvis being normal she was allowed to go into labour. The first stage, assisted by morphine, lasted fourteen hours, the second stage two and a half hours. After delivery of the child a gap in the anterior wall could be felt. As there was considerable loss the placenta was removed manually. Operation was decided on, and though there was no sign of free fluid in the abdomen the patient became shocked and was given a blood transfusion of 500 c.cm. Panhysterectomy was performed under spinal anaesthesia. There was little blood in the abdomen and no signs of adhesions to the ruptured scar. The scar showed, at the point of rupture, a poorly developed network of fibrous tissue. It was of interest that the child could be delivered naturally in the presence of a rupture of the uterus.

Professor DOUGAL showed an unusually large mucous cervical polyp in a patient, a nullipara aged 25, married one year. She complained of five weeks' severe loss following five months' amenorrhoea. A large friable mass was felt filling the vagina. On microscopical examination this was found to be an extremely active but benign adenoma of the cervix. On this finding it was decided to remove the growth locally, which arose from the posterior wall of the cervical canal. The patient went home in good condition a week later. Professor MILES PHILLIPS said he had had a similar case, which later became very actively malignant. He doubted very much if these large cervical adenomas should be considered benign so far as the future was concerned. Professor DOUGAL said he had seen the patient four months after operation, and there was so far no sign of recurrence.

Professor DOUGAL gave a cinematograph demonstration of an operation on a huge procidentia. This was the largest he had seen. The patient was aged 47, had one child, now 21, delivered by forceps, and had complained of "dropping of the womb" for nearly twenty years. The operation performed was the Fothergill modification of the Donald colporrhaphy. Professor Dougal had operated on procidentias of varying size, and had found that the combined amputation of the cervix and double colporrhaphy never failed to cure the condition.

TREATMENT OF VESICULAR MOLE

Professor LEITH MURRAY read a paper on the treatment of vesicular mole. He had been stimulated to read this paper by a remark he had heard at the meetings to the effect that abdominal hysterotomy for vesicular mole was indefensible. He considered the condition a grave one, and though the fourteen cases he now reported did well he had, in his younger days, seen many desperate cases result from evacuation from below. The recorded mortality ranged between 10 and 25 per cent. Vesicular mole was a disease occurring in women old enough to have further pregnancies. It had a slight but definite tendency to malignant transformation, carried an inherent tendency to serious haemorrhage, and, when treated inauspiciously, a risk of sepsis and perforation of the uterus. He recommended the operation of abdominal hysterotomy for this condition. Even with a large mole it was almost bloodless. A dry swab easily and rapidly evacuated the whole mole in a few seconds, the mole coming away practically intact within a brownish capsule of decidua. After this the uterine wall could be easily inspected for signs of penetration or haemorrhagic infiltration. This treatment was carried out in four of the fourteen cases reported. Of the ten not so treated two developed chronic epithelioma later, and though there was no case of sepsis in the series, in two bleeding was leading to a visible anaemia. Of the four treated by abdominal hysterotomy, two had since borne full-term children. In one, aged 49, hysterectomy followed the hysterotomy on account of age. The third, who had not since had a child, was aged 39, and had two fibroids removed at the same time.

THE SEDIMENTATION TEST

At a meeting of the Section of Pathology of the Royal Academy of Medicine in Ireland, held in the Royal College of Physicians on November 20th, with the president, Dr. J. T. WIGHAM, in the chair, Dr. A. R. HALPENNY read a note on the sedimentation test.

In the course of discussion, the PRESIDENT expressed the view that if this test could be performed with a smaller quantity of blood than 8 c.cm. it would be easier to carry out. He felt that the same rate of sedimentation would be obtained if the tube used were narrow or wide. After asking whether age made any difference, he gave it as his opinion that the rate might possibly increase with advancing years.

Dr. SPENCE SMYTHE said that during the last eight months the sedimentation rate had been estimated in the

Rotunda Hospital in various cases of pregnancy. As controls, twelve normal non-pregnant women were taken, in all of whom the sedimentation rate was 120 per minute or over—a perfectly normal figure. During the child-bearing period, age did not seem to affect the sedimentation rate at all. The test was really of no use as a test for pregnancy because the rate was not accelerated before definite clinical evidence of pregnancy was present. In one case of hyperemesis gravidarum, the rate was much delayed for the particular time of pregnancy. This might have been due to the fact that the patient had been starved in the course of treatment. In eight cases of normal puerperium where food was given, the rate, one and a half hours after a meal, was definitely delayed. The giving of anti-streptococcal serum intramuscularly also delayed the rate. In puerperal sepsis of uterine origin the rate was much accelerated, and took a very long time to return to normal. Anaemia caused no increase in the rate.

Dr T. T. O'FARRELL said that figures for this test had been given in Parkinson's disease, and the question arose as to whether one got different results when that disease followed encephalitis lethargica. He had done the test in a few cases, and those which were of the ordinary type showed a more rapid drop in rate than did the post-encephalitic cases. Dr. T. W. T. DILLON said that in cases of lung tuberculosis, this test had proved to be of no value in diagnosis, but it had been found useful as a prognostic test. In cases of bone tuberculosis, however, it was extremely valuable. Personally he regarded this test, together with accurate estimations of weight, as even more important than the keeping of a temperature chart.

Dr HALPENNY, *in reply*, said that all her patients had had 8 c.cm. of blood removed from the vein. She found this preferable to taking blood from the finger. Any slight inaccuracy in the carrying out of the test might be accentuated by using a small amount of blood. All her patients were under 30 years of age. She had had no opportunity of using the test in a case of Parkinson's disease.

CARCINOMA OF APPENDIX

Mr F. J. HENRY showed a specimen of carcinoma of the appendix. The patient, a young woman aged 22, was admitted to hospital with a typical attack of acute appendicitis. It was her first attack which, when she was seen, appeared to be subsiding. Operation revealed an acutely inflamed but unperforated appendix with a single concretion at the distal end and a nodule of solid yellow tissue immediately above it. Mr. Henry briefly reviewed the literature dealing with these tumours, in reference to the statements of Wilkie, McQueen, and Shera, who had reported similar cases.

Dr J. LAIT described the pathological condition.

The PRESIDENT suggested that this was a case of infiltrating carcinoma. He did not think it was a basal-celled tumour. Mr A. B. CLERY referred to two cases of carcinoma of the appendix recently under his care. In both cases metastases formed, the cancer being of the colloid type.

Dr T. T. O'FARRELL said that in cases of carcinoma of the intestinal tract, yellow pigment was frequently seen. He thought this might be a secondary tumour, and regarded it as being of the scirrhous type. He could not believe that a specimen could be genuinely malignant microscopically and fail to prove malignant afterwards.

Mr D. J. TORRENS referred to tumours which were described as argentine carcinomata (because the cells stained with silver nitrate), and mentioned that in the Mayo Clinic this condition was said to occur in about one out of 250 cases examined. In some cases the patients were over 60 years of age. He mentioned one case in a man aged 39, and another he had seen in which metastases had been found in the testis eight years after operation. Most of the cases which were recorded were, clinically, cases of acute intestinal disease.

Sir WILLIAM WHEELER deprecated the use of the term "carcinoma" in connexion with these unusual tumours of the appendix. Cases of carcinoma occurring in young people grew rapidly and destroyed life by early metastatic glandular involvement. The type of growth under discussion was found almost without exception in young people, and there was a striking absence of metastases. He did not regard these growths as malignant in the accepted sense of the word. The term "carcinoma," when applied to a tumour removed from a young subject, suggested to the clinician that metastases were to be expected and that the prognosis was unusually bad; the exact reverse was the fact in cases of so-called carcinoma of the appendix.

SARCOMA OF TESTIS

Mr. F. J. HENRY showed a specimen of sarcoma of the testis. The patient was a man aged 22. For two months he had noticed a hard enlargement of the right testis, which had increased progressively until it had attained the size of a grape fruit. The swelling was nodular, particularly at the posterior part, where it simulated the clinical features of tuberculous disease. The testis and epididymis were removed through an inguinal incision. The macroscopic appearances of the sectioned organ showed a fibrous stroma with scattered areas of necrosis. Early recurrences in the iliac lymph glands had taken place, but these were yielding in the most dramatic way to deep *x*-ray therapy. Dr. J. LAIT described the pathological condition, the tumour being, in his opinion, a seminoma.

The PRESIDENT said that testicle tumours were usually mixed tumours. He thought that this tumour was a genuine carcinoma and not a sarcoma, and that the cells were more of an epithelial than of a connective tissue nature. Dr J. MCGRATH agreed that this tumour was a seminoma; it seemed to him to have the typical features. The cells were large, had large nuclei, and extended in sheaths arranged round the blood vessels. The only thing against a seminoma was the patient's age, for these tumours usually occurred in men between 40 and 50. Dr T. W. T. DILLON thought there was a difference between the cells which were in sheath formation and those which were arranged round the blood vessels.

Dr LAIT and Mr HENRY replied, the latter stating that from the clinical point of view this was a tumour of excessive malignancy.

At a meeting of the Aberdeen Medico-Chirurgical Society held on December 3rd, with the president, Mr F. K. Smith, in the chair, Mr. Norman M. Dott of Edinburgh read a paper on the surgery of the posterior cranial fossa *in childhood and adolescence*. Mr Dott discussed in detail the three commonest lesions—chronic basal leptomeningitis, astrocytoma, and medulloblastoma of the cerebella vermis, as exemplifying an inflammatory disease, a benign tumour, and a malignant tumour. Several illustrative cases of these conditions were demonstrated, and the diagnosis and treatment were described. Mr Dott also mentioned tumours of the pituitary neighbourhood, gliomas of the cerebral hemispheres, benign meningiomas of the convex surface of the brain, angiomas, tumours of the cerebello-pontine angle, and trigeminal neuralgia, giving illustrations of several of these conditions to bring out the particular methods of diagnosis and surgical treatment required for each. Mr WILLIAM ANDERSON, Dr A. G. ANDERSON, Professor CRUICKSHANK, Sir ASHLEY MACKINTOSH, Mr G. H. COLT, and Dr J. Ross MACKENZIE, took part in the discussion following Mr Dott's address, and Sir John Marnoch expressed the appreciation of the large audience.

increasing belief that the "bistouri diathermique," or other suitable electrode, will revolutionize surgery, particularly in its relation to the cure of cancer. The treatment of accessible cancers and tumours by diathermy coagulation has yielded results beyond all hopes, and in certain cases quoted has proved superior to x rays and radium. The chapter on cancer of radiologists shows that diathermy coagulation has brought fresh hope to the treatment of radium dermatitis. This treatment has also been successful in cases of lupus where actinotherapy was not suitable—that is, where the lesion was extensive and deep, and the patient anxious for a quick cure and less concerned with the good cosmetic result achieved by light. The author supports his observations with convincing notes and photographs of the patients he has treated.

As long ago as 1919 Dr. Bordier was using diathermy coagulation in treating tonsillar hypertrophy and infection, and continues to find the results all that he wishes for. There is never any haemorrhage, the bactericidal effect is enormous, and the scar non-adherent and supple. He has treated children with success, but does not advocate this method for those under 10 years. His original treatment of anterior poliomyelitis, combining radiotherapy and galvanization with diathermy, is now being practised by many electrotherapeutists.

To the casual observer, this book may seem to be advocating diathermy as a universal remedy, but on closer study it is obvious that the author speaks from a thorough experience, and has a sound basis for his statements.

CUTANEOUS RAY THERAPY

During the last twenty years actinotherapy in one form or another has become increasingly important in the treatment of skin diseases, and in particular the debt owed by dermatologists and their patients to the healing powers of x rays and radium has become incalculable. Nevertheless, there have not been many practical handbooks written on the subject, and consequently we welcome Dr. H. H. HAZEN's volume on *Cutaneous X-ray and Radium Therapy*.[5] Dr. Hazen is a dermatologist of very great experience in this subject, and the methods and technique which he describes can be safely followed. There is, however, one great difference between American and European practice in the measurement of x-ray dosage. On this side of the Atlantic we are still accustomed to rely on the Sabouraud pastille, while in America (owing apparently to the dryness of the atmosphere) it has proved unsatisfactory, and hence Americans for the most part use an arithmetical formula, which has to be worked out separately for every x-ray tube. In consequence of this, gas tubes, the output of which varies considerably, are almost extinct in America, and their place is taken by the Coolidge tube, which lends itself to comparatively easy standardization.

Dr. Hazen's remarks on the action of radiation upon pathological tissues are very interesting. He does not believe that the cure of cancer depends upon the direct destruction of cancer cells, and thinks that the work done by those who have spent their energies in searching for the lethal dose necessary in dealing with various forms of cancer has been largely wasted. He believes that the tissue reaction is the central factor in the cure. His discussion of this very important and interesting subject is well worth reading. The importance of radiation as a therapeutic agent is brought home by his classification of skin diseases amenable to its effects. These are classified into thirteen groups, ranging from those in which radiation gives good results with or without the aid of other therapeutic agencies, down to a group of rare diseases in which radiation has occasionally been successful. Perusal of this list shows quite clearly how wide is the scope for actinotherapy in dermatology. In some conditions the x ray, and in others radium, is the agent of choice. In the treatment of plantar warts much better results are claimed for radium than for x rays, but the difficulty which these troublesome lesions give to the dermatologist is proved by the very odd confession that very old warts are so difficult to handle that they are best left untreated. In our opinion, even the most stubborn will yield to a suitable combined therapy. We have but little else to cavil at in an excellent and practical book, which should be read alike by dermatologists and by those radiologists who interest themselves in the problems of superficial therapy.

[5] *Cutaneous X-ray and Radium Therapy*. By Henry H. Hazen, M.D. London: H. Kimpton. 1931. (Pp. 166; 28 figures. 12s. 6d. net.)

NOTES ON BOOKS

The fifth edition has now appeared of Professor HERRICK'S textbook, *An Introduction to Neurology*.[6] With the increase of knowledge now available the subject-matter has been thoroughly revised and the details brought up to date. The main part of the book consists of a detailed account of the anatomy and physiology of the brain and nervous system; the illustrations are clear and the index is good. Controversial difficulties, such as the functions of the cerebral cortex, are dealt with thoughtfully, and the book will be welcomed by those who wish to place their neurological knowledge on a sound basis.

The seventh edition of *Bainbridge and Menzies' Essentials of Physiology*[7] has been again revised by Professor H. HARTRIDGE, who contributes new chapters on the basic principles of the blood, the heart, the circulation, respiration, the autonomic nervous system, the digestion, the metabolism, the kidneys, ductless glands, and sex organs. The account of the central nervous system has been rearranged with a view to clarifying the information. In the previous issue—which appeared in 1929—the chapters dealing with the sensory nervous and muscular aspects of physiology were rewritten by him. The whole volume is now up to date; it can be warmly commended to medical students and others interested in elementary physiology.

The appearance of a fourth edition of the well-known book *Tropical Hygiene*,[8] by the late Sir PARDEY LUKIS and Colonel BLACKHAM, is in itself the best testimony to the useful purpose which it serves. The present edition has been revised by Lieut.-Colonel A. D. STEWART, and chapters on sprue, filariasis, relapsing fever, leprosy and typhus, maternity and child welfare, etc., have been added. The aim is to provide a book on elementary hygiene which will appeal to the ordinary resident in the Tropics, and peculiarly in India. This aim has been well fulfilled. The book is admirably conceived, its scope has been carefully chosen, and the subject-matter, though intended for the non-medical reader, is treated in a properly scientific manner, and opinion when expressed is well balanced. Communicable diseases in the Tropics and the part played by insects, climatic conditions, water, food, nutrition, clothing, housing, and sanitation, are dealt with in turn as in a large textbook. Its chief use will be

[6] *An Introduction to Neurology*. By C. Judson Herrick, Ph.D. Fifth edition, thoroughly revised. Philadelphia and London: W. B. Saunders Company. 1931. (Pp. 417; 138 figures. 12s. 6d. net.)

[7] *Bainbridge and Menzies' Essentials of Physiology*. Seventh edition. Edited and revised by H. Hartridge, M.D., Sc.D., M.R.C.P., F.R.S. London and New York: Longmans, Green and Co. 1931. (Pp. x + 583; 166 figures. 14s. net.)

[8] *Tropical Hygiene*. By the late Surgeon-General Sir Pardey Lukis, K.C.S.I., and Colonel R. J. Blackham, C.B., C.M.G., C.I.E., D.S.O., M.D., D.P.H. Fourth edition, revised and enlarged by Lieut.-Colonel A. D. Stewart, M.B., F.R.C.S.E., D.P.H., D.T.M. & H., I.M.S. Calcutta: Thacker, Spink and Co. 1931. (Pp. xi + 441; 79 figures. Rs.5.)

as it is intended to be, for those resident in India and the East; for this reason plague in South Africa, trypanosomiasis, and American leishmaniasis find no place; also it may be mentioned that venereal diseases, yaws, and schistosomiasis are not dealt with, and helminth injections outside ankylostomiasis receive but scanty notice.

Minor Surgery,[9] by the late Mr. L. R. FIFIELD, has now been revised by his colleague Mr. R. J. MCNEILL LOVE, who has preserved in the second edition the general style and arrangement which proved so acceptable to many readers. Certain additions have, however, been made in regard to the examination of the patient, and a short section on the ear has been included, dealing with the presence of foreign bodies, rupture of the drum, acute otitis media, and furunculosis of the external ear. The new edition will be welcomed by students and practitioners who desire a short practical summary of minor surgery clearly expressed and well indexed.

The formation of the National Government and the subsequent general election have brought about many changes in the sixty-fourth annual issue of *Whitaker's Almanack*,[10] published early in December in order that it may be available for transmission over-seas before the end of the year. The Cabinet as reconstructed and the New House of Commons are included, together with articles on the financial crisis and government by party. Statistical tables are also provided to show the source of the world's food and other products, and the quantities and places of origin of Great Britain's food imports. The preliminary results of the Census are recorded. The index has again been enlarged, and now consists of 140 columns, containing upwards of 20,000 references.

The recent financial and social conditions in Germany probably account for the fact that since the commencement of this year there has been a marked slowing-down in the appearance of the various volumes of the third edition of Kolle and v. Wassermann's *Handbuch der pathogenen Mikroörganismen*,[11] which is being published seriatim. We have now received three further Parts—48, 49, and 50. The last of these is indicated as the conclusion of the whole series, and contains a general detailed index, a list of authors, and an analysis of the contents of each of the preceding volumes. Part 48, which is concerned entirely with dysentery, has been prepared by the capable hands of Professors O. Lentz of Berlin and R. Prigge of Frankfort. As in the case of the rest of this series, a great amount of minute detail is compressed into the volume, which will thus be of more particular interest to research workers. Part 49 contains an account of paratyphoid infections, prepared by Dr. G. Elkeles of Berlin and Dr. R. Standfuss of Potsdam. Each volume includes a comprehensive bibliography, and these three final Parts form a fitting conclusion to a work of high merit.

The series of French books entitled Précis de Pathologie Médicale[12] is being issued in eight or nine volumes, of which some have already appeared and others are in course of preparation. The third volume, on respiratory diseases, by F. BEZANÇON and S. I. DE JONG, has reached a second edition, and the fourth volume, on diseases of the heart and vessels, by M. A. CLERC and N. DESCHAMPS, has recently been issued. These well-illustrated books aim at giving to medical students and practising physicians a general review of the pathological aspects of disease, the subject being approached from the clinical rather than from the purely pathological point of view. The complete series is a valuable addition to a medical library, and the two volumes which have just appeared maintain the high standard previously reached.

[9] *Minor Surgery*. By Lionel R. Fifield, F.R.C.S. Second edition, revised by R. J. McNeill Love, M.S., F.R.C.S. London: H. K. Lewis and Co., Ltd. 1931. (Pp. viii + 440; 281 figures. 12s. 6d. net.)

PREPARATIONS AND APPLIANCES

A NEW SUTURE-HOLDING FORCEPS

Mr. W. H. OGILVIE, F.R.C.S., writes: The continuous suture, rare on the Continent but almost universal in Britain, requires that the material shall be held taut after each stitch, to prevent slack developing in the suture line. In most surgical operations this is best done by the hands of the assistant. In bone and joint surgery, where "no touch" methods are an essential part of good technique, this is not permissible, and the surgeon must either use interrupted stitches or employ some form of suture-holding forceps. The usual patterns have metal jaws which, though smooth, weaken the suture material considerably where they grip it, so that it may break at the time or afterwards, allowing the whole length of the suture line to gape. This accident is very liable to happen with the fine 00 catgut usually employed for tendon suture, for approximating the synovial membrane and capsule of a joint, or for closing the soft tissues over a bone. Down Brothers have made for me a pair of suture-holding forceps, whose general design is that of the familiar

Guy's pattern, but whose blades end in a rounded loop open at one end, over which is slipped a length of fine rubber tubing. The rubber gives a secure grip, but cannot injure the finest gut; it can, of course, be renewed when worn.

OUABAIN

Ouabain (Burroughs Wellcome and Co. is a crystalline glucoside extracted from the seeds of *Strophanthus gratus*. In virtue of the fact that it can be obtained in a chemically pure form this substance has been adopted in certain countries as the standard of reference for the bio-assay of cardiotonic drugs. For clinical use it has the advantage of being a pure crystalline substance readily soluble in water.

BIOLOGICAL TREATMENT OF ORAL DISEASE

Spirogyl ointment for massage of the gums is stated to contain 35 per cent. of fuso-spirochaetic antivirus. Besredka showed that heated filtrates of microbic cultures could produce local immunity, and Séguin investigated the action upon lesions of the gums of filtrates of this kind prepared from the flora of the mouth. He concluded that they produced a beneficial action, and the preparation under consideration is based on this work. The makers claim that it has given satisfactory clinical results. It is marketed by Sealand Trading Co., Ltd.

COLLOIDAL MERCURY SULPHIDE

Mercolloid (Bio-Chemical Laboratories, Ltd., Locarno is a preparation of mercury sulphide in colloidal form. It is supplied in ampoules for intramuscular injection. The makers claim that the injections are painless, that the drug is well tolerated, and that it has a powerful treponemicidal action. It is recommended for the treatment of syphilitic and parasyphilitic conditions, and also for the treatment of psoriasis. Chemical analysis of a sample supplied to us showed that about four-fifths of the mercury sulphide was suspended in colloidal form, whilst the remainder had formed a precipitate.

BRITISH HYPODERMIC NEEDLES

British Surgical Industries, Ltd. 14, Regent Street, S.W.1 have placed on the market their new all-British stainless steel hypodermic needles. It is claimed that the quality is superior to that of needles of Continental manufacture, which have for so long been in general use; the prices at which they are retailed compare favourably with those of the foreign articles.

British Medical Journal

SATURDAY, DECEMBER 12th, 1931

CARCINOMA OF THE HYPOPHARYNX

The treatment of carcinoma in the lowest part of the pharynx, situated behind the larynx and immediately above the junction with the oesophagus, presents a surgical problem of great complexity. The primary functions of respiration and deglutition have to be maintained, and, if possible, it is most desirable to provide for phonation also by preserving the larynx. Further, the treatment planned must take into consideration the common routes of extension and the usual sites of metastases, besides the difficulties in controlling septic infection inherent in the surgery of the pharynx. These tumours, which are not very rare, occur chiefly in women immediately behind the plate of the cricoid cartilage, but there is also a male group in which the tumour is situated on the posterior pharyngeal wall. In women the tumours often arise a decade or two before the time at which carcinoma usually appears, and are constantly preceded by a long period of slight dysphagia. Early diagnosis is therefore exceptional, and the growths tend to spread down to the cervical part of the oesophagus, up towards the pharynx, and laterally into the thyroid gland before the nature of the complaint is recognized.

The discussion of this subject, initiated by Mr. Wilfred Trotter at the Laryngological Section of the Royal Society of Medicine on December 4th, provided an opportunity to review the various therapeutic measures, any of which may give a brilliant result, but are more often unsatisfactory owing to the situation and character of the disease. The most drastic surgical operation is that devised by Professor Gluck. The entire larynx, with a complete segment of the lower pharynx, is removed, along with the cervical lymphatic glands of both sides; the pharynx is reconstructed six months later by a plastic operation, and the patient is left with a tracheal stoma as after a simple total laryngectomy. Professor Gluck has long advocated this operation, on the ground that no attempt to preserve the larynx is compatible with a reasonable expectation of freedom from recurrence, and that the separation of the airway from the pharynx is a protection against inhalation pneumonia. Although a severe mutilation is produced by the operation, it is capable of giving a brilliant and lasting result. In this country, however, Mr. Trotter has long protested against laryngectomy, and has advocated an operation which removes the tumour and its extensions freely, but retains both the larynx and the pharynx as far as possible, the portions removed being reconstructed by means of skin flaps. Mr. John Hunter gave an account of the technique to be followed in the varying circumstances which may arise in such undertakings, devoting himself to this aspect of the question in greater detail than Mr. Trotter, who gave a general description of those pharyngeal tumours which take origin around the larynx, and of the principles underlying their surgical treatment. He related a number of cases in which the patients had survived many years without recurrence and without serious mutilation.

Professor Carl von Eicken of Berlin also gave a general review, in which he outlined the pathology of tumours which arise in the hypopharynx. They differ from those of the epilaryngeal group, which grow more slowly and form metastases later than do tumours which originate in the sinus pyriformis and lowest part of the hypopharynx. Microscopically, many of these tumours are of the anepidermoid or mucous type of epithelioma, indicating that a certain proportion might prove sensitive to ray therapy. He considered that on the whole purely surgical treatment was unsatisfactory on account of the technical difficulty of the operations, the mortality from sloughing, cellulitis, and pneumonia, and the necessity for subsequent plastic operations. He had therefore sought a solution of the problem in radiological treatment, and related some encouraging results. The application of radium to tumours of the hypopharynx can be carried out either by external application with a pack or in combination with surgery. The latter method had been used in eleven cases without producing any complication, and in two cases the tumour had disappeared, leaving the patients free from symptoms, whilst in five of the remaining nine the tumour had diminished in size. He had no personal experience of radiotherapy by deep x rays, but he thought that the method of Coutard, who employs protracted fractional doses by exposing the patient to treatment for one hour daily over a period of three weeks, was very promising. Coutard claimed 20 per cent. of permanent cures, a better result than could be claimed for surgical intervention.

Mr. Douglas Harmer admitted that so far the results of deep x-ray therapy had been disappointing, but he thought that a combination of surgery and radium with deep x rays, provided by an apparatus of the requisite strength, would show improved results. He gave a warning about the stimulating effect on tumour growth of inadequate x-ray treatment. Mr. Mollison also described what has been accomplished by the deep x-ray department at Guy's, where an apparatus of sufficient power is available. The discussion tended to show that in the hands of Mr. Trotter the surgery of this region has reached its zenith. Those, however, who hold that any further advance in treatment is likely to be along lines which are not purely surgical would do well to bear in mind some words used by that surgeon a few weeks ago: "It is commonly supposed that the use of radium has greatly simplified the treatment of epithelioma of the pharynx. This supposition is not true. Radium has given us a new and very powerful addition to our means of attack, but so far from simplifying the attack has made it more than ever dependent on experienced judgement and expert handling. It is possible even that up to the present time the total

results as to cure or notable periods of freedom from recurrence are actually worse for the introduction of radium, since it seems likely that many patients who might have had a good chance of cure by operation in competent hands have had their chance frittered away in ineffective radium treatment. If this is so it is, of course, only a transient phase, for a proper appreciation of the technical requirements of sound radium treatment is already replacing the cruder view and must in time result in the full benefits of radium being made manifest."[1]

The general conclusion reached at last week's meeting may be summed up as follows. In relatively early cases, where the larynx, the thyroid gland, and the upper end of the oesophagus have not been invaded, the treatment of choice is the operation of Trotter. A segment of the pharynx containing the growth is excised and replaced by a flap of skin turned into the wound from the surface of the neck. In more advanced cases the operation of Gluck is capable of giving the patient a long period of freedom from the disease with a tolerable functional condition, but with the sacrifice of the larynx. On the other hand, where no operation can be undertaken, or when it is declined, the use of deep *x* rays or of radon seeds, implanted around the tumour either into an open wound or through the skin of the neck, may provide great relief from dysphagia or even a long period of freedom from active disease. Even if the initial treatment be successful, whether it be surgical or radiological, it is unfortunately not improbable that the patient will succumb in the end either to a local recurrence or to invasion of the mediastinal glands. Nevertheless, we may echo the hope entertained by Mr. Trotter "that the number of cases of the severer type will diminish when the natural history of these growths becomes more generally known, and it is learnt that diagnosis is usually easy at an early stage if one knows what to look for."

SERO-DIAGNOSIS OF SYPHILIS

Uruguay is to be congratulated on having staged a serum conference at Montevideo last year in continuation of those held at Copenhagen in 1923 and 1928. The diagnosis and determination of cure of syphilis by serum tests are so important, and at the same time so difficult, that every encouragement should be given to those who are anxious to improve and correlate the methods at our disposal. The campaign against syphilis —only really launched at the beginning of this century —depends very much for its success on perfecting the various serum reactions. So long as pathologists remain in watertight compartments, carrying out their own favourite reactions, little progress will be made. It is only by getting them together and comparing their results—both with each other and with the clinical findings—that the relative value of the various methods can be assessed. In this conference twelve methods were considered—namely, seven modifications of the Bordet-Wassermann, four flocculation, and one sero-haemo-flocculation. It will be useful to compare these with one another in respect both of sensitiveness and of specificity.

Four of the Wassermann methods, one flocculation, and the sero-haemo-flocculation method gave such a high percentage of false positive results that they may be dismissed at once. The Kahn "presumptive" test gave by far the highest percentage of positive results in syphilitic serums, with three false positives in non-syphilitic ones, while it held its own with the other tests in the case of cerebro-spinal fluids, but gave four false positives out of 142 non-syphilitic specimens. Its principal value, therefore, is as a test of cure and to exclude syphilis—for example, in blood donors. There remain three Wassermann methods (Scaltritti-Cassiniga, Sordelli-Miravent, and Wyler) and two flocculation methods (Kahn "standard" and Müller—M.B.R. II). Of these the Kahn and Wyler are outstanding as having yielded no false positives in the whole series of 966 serums and 200 cerebro-spinal fluids—a very remarkable achievement. The Kahn test, however, was much the more sensitive, giving 63.9 per cent. as against 54 per cent., and 35 as against 28 positives in syphilitic serums and cerebro-spinal fluids respectively. The Müller (M.B.R. II) reaction came out very well in respect of sensitiveness, but gave two false positives on serums and one on a cerebro-spinal fluid. Of the three Wassermann methods none recorded a false positive on a serum, while their percentages of positives on syphilitic serums were: Sordelli-Miravent, 55.9; Wyler, 54.4; Scaltritti-Cassiniga, 49.9. In the cerebro-spinal fluid series the Sordelli-Miravent method was not employed; Scaltritti-Cassiniga recorded 39 positives out of 52 in syphilitic cases, and one false positive out of 147 non-syphilitic; Wyler out of 53 syphilitic cases recorded 28 positives, and had no false positives in the non-syphilitic group; moreover, he had 10 "doubtful" reactions in the syphilitic group, which would probably have been recorded as weak positives under less exacting conditions, since he had none among the non-syphilitics. Speaking generally, the complement-fixation reactions quite held their own with the flocculation reactions in the case of cerebro-spinal fluids; this is a matter of some importance, since the Kahn test, for example, is laborious to carry out on cerebro-spinal fluids, and does not work well with specimens which are not clear; such specimens are, unfortunately, all too common in everyday practice.

To sum up, the Kahn standard test must be given the palm both for specificity and for sensitiveness. Of the Wassermann methods three proved almost equally reliable, though not quite so sensitive as some of the flocculation tests. However, in view of the fact that in a certain number of cases of syphilis the Wassermann reaction was positive when the flocculation test was negative it would appear that, as a routine, two methods —one a Wassermann test and one a flocculation— should be employed on all serums. This was recommended after the Copenhagen conference in 1928, and

[1] Wilfred Trotter: Some Principles in the Surgery of the Pharynx. Address at the Central London Throat Hospital. *Lancet*, October 17th, 1931.

also after the conference under consideration. An interesting side-line was the testing of twenty-seven serums from cases of leprosy; about one-third of these gave positive results in the hands of most of the workers. A general agreement was obtained as to the recording of results: ++ or + indicating a positive, ± a doubtful, − a negative. If pathologists all over the world would adopt his method a good deal of doubt and misconception would be avoided. The value of the conference cannot be overestimated, but there is one point which does not seem to have been discussed, and that is a really good eliminating test. What is needed is a highly sensitive test—easily and quickly carried out, and applicable to large numbers of specimens. This might be used as a routine; then those serums giving positive results might be tested further by one or other of the methods that have been proved satisfactory. This would save a vast amount of time for those pathologists who have large numbers of specimens to deal with.

The report of the Montevideo conference is well got up and clearly printed.[1] Tables are included giving a summary of the results obtained by the various serological methods, and also the detailed results obtained on each individual specimen. Each specimen was divided up among the various workers and labelled only with a number, so that its origin and the clinical diagnosis were not disclosed till the end.

THE HISTORY OF ERGOT

The history of drugs is in many cases a long and curious story that runs back to classical times and even earlier. This interesting subject suffers, however, from an undeserved neglect, because few people have either the patience or the varied knowledge necessary for its pursuit. The history of ergot begins with the epidemics of ergotism, one of the many horrors, now half-forgotten, that afflicted mediaeval Europe. Professor Barger[2] has given a full account of these epidemics from the ninth to the nineteenth century, with numerous quotations from original documents and interesting mediaeval pictures depicting the evil effects of ergotism. These epidemics were of two kinds, the gangrenous and the convulsive, and the reason for this distinction has, until recently, been a mystery; but investigations by Mellanby suggest that convulsive ergotism may have been due to ergot poisoning combined with lack of vitamin A. Professor Barger shows by quotations that clinical observers in the past were convinced that convulsive ergotism could be prevented by the addition of butter and eggs to the diet. Hence, a half-forgotten clinical observation has been confirmed and explained by recent scientific work. The tragic experience of epidemic ergotism led to recognition of the abortifacient action of ergot, and the drug, first used as a folklore remedy, was finally recognized and employed by the medical profession. Professor Barger's account of the chemistry of ergot has special importance, because the author is one of the chief authorities on this subject. Chemical research on ergot, while presenting great difficulties, has yielded results of extraordinary interest, for the fungus has proved to be a veritable storehouse of substances of first-rate biological significance. The specific alkaloids are the substances to which the drug owes its clinical value; moreover, it was in this material that histamine and ergosterol were first discovered. Professor Barger, indeed, concludes that the general interest of ergot is greater than that of any other drug. Barger and Carr found that the chief active alkaloid of ergot of rye was ergotoxine, and this has been confirmed recently by Smith and Timmis. Stoll, however, found that ergotamine was the chief alkaloid present. One point of considerable practical interest in the clinical use of ergot is that, since the introduction of ergotamine, a number of cases of severe gangrene have been attributed to it by certain authors. Chapters on the chemical and biological assay of ergot, the sources of supply of the drug, and the methods used for estimating whether ergot-infected rye is suitable for human consumption, conclude the monograph. It therefore deals with a wide variety of subjects, and provides a remarkably complete and very interesting account of the use of ergot as a drug and of its action as a poison.

PARASITOLOGY IN CHINA

Modern parasitology is very intimately connected with China. It was there, in 1878, that Patrick Manson carried out the fundamental work on filaria which introduced to medicine the conception of the biting intermediate host. It was there that Leiper, in 1913, found the clue to the life-histories of the African blood-flukes, and later it was there, too, that Faust and Cort and other American workers conducted some of their most important researches. That China, though no longer a virgin field, still offers an inexhaustible wealth of material for scientific research, is well shown by the August–October number of the *National Journal of China*, which is entirely devoted to original articles on protozoa, helminths, fungi, and their treatment and prophylaxis. The wide ground covered by the twenty-two articles indicates that China's own sons are now giving parasitology the attention it merits. In a leader the editor discusses the general ignorance of medical practitioners on the subject. This he believes is due to the fact that students returning from abroad know little or nothing about parasitology because it is either omitted entirely or else inadequately taught in the ordinary medical schools. Except in countries with tropical possessions, it is not considered advisable to burden the medical student with what is unnecessary for his future career. Even in countries with tropical possessions parasitology is not included in the ordinary medical curriculum to any extent, but is reserved for study in post-graduate diplomas. Undoubtedly this criticism is true, but in these days of overcrowded curricula it seems unfair to suggest adding to the ordinary course instruction which only has an extraordinary application, and which in any case is provided for in special courses intended for medical men proceeding to the Tropics. There are three such courses in Britain—in London, Edinburgh, and Liverpool—and these seem to meet most requirements. The criticism is, however, more to the point in suggesting that what

little parasitology is necessarily included in our M.B. courses is not adequately, and often not even accurately, taught. There should be no excuse for lack of accuracy in the teaching of the subject in this country: only half a dozen worms or so are important, and sufficient information can be easily obtained; and yet the most profound ignorance persists. The real solution of China's problem would seem to lie in the provision of more and better local instruction. The position is appalling. In a commencement address at Peiping by Hu Shih (reported in the same issue) it is pointed out that the proportion of modern-trained doctors to the population in the interior cannot be more than one to every million inhabitants. In the old days the Chinese doctor could, somewhat empirically, prescribe for the more common diseases; but he is quickly dying out without being replaced, because the products of the modern secondary school are unwilling to master the mysteries of the ancient profession, which they know must sooner or later give way to the modern medicine from the West. In Hu Shih's own district a population of half a million people is relying in matters of life and death on an opium-smoking quack doctor. The need for modern physicians is extreme in the interior, where curable diseases and preventive epidemics kill thousands, and where millions of lives are resigned to fate and ignorance. In her efforts to solve the problem China has a right to expect assistance from the modern medical science of the West.

FOOD PRESERVATION

It is only about fifty years since the first consignment of frozen meat from Australia was delivered in sound condition at the London docks. In this brief period an industry has grown up which now employs over a thousand vessels, with a total cargo capacity of about a million tons. These figures, which are given in an introductory note to the first number of vol. iii of the *Index to the Literature of Food Investigation*,[1] issued by the Department of Scientific and Industrial Research, are instructive from several points of view. We are not here concerned, however, with their political, economic, or sociological implications, but with the need they suggest for continuous scientific research in preserving the quality and freshness of the natural product. In this connexion the publication referred to above contains some illuminating information, which reveals incidentally how various branches of inquiry are being turned to practical account. Thus, Tadokoro and Watanabe in Japan are reported to have made some interesting observations on the chemistry of fish muscle, while Linneweh and his co-workers have investigated the constitution of "anserine" and its presence in the muscles of different birds. In this country the importance of physico-chemical considerations to storage problems was indicated at the meeting of the Faraday Society held at Cambridge last year, when reference was also made to work on the double refraction of muscle. "It not only promises to close the century-old controversy about the structure of striated muscle fibres, but also reopens that too much neglected theory of the structure of fluid which began with Poisson and seemed to end with Poynting." In regard to by-products a bulletin issued by the Hannah Dairy Research Institute, describing an inquiry into the utilization and marketing of surplus milk and milk residues during 1926, concludes that the amount of separated milk wasted in Scotland was sufficient to furnish the whole of the Scottish imports of condensed separated milk. Another subject that has been recently investigated by various workers is the deterioration of animal and vegetable fats on storage. It has been found that the three main factors responsible for the production of objectionable taste, odour, and appearance are moulds and bacteria, atmospheric oxidation, and tissue enzymes, and that any combination of these may cause rancidity. Studies on the gas storage of fruit appear to have shown fairly conclusively that this method of preservation has become a commercial proposition, and attention is now being directed, especially in America, to the effects of cold storage, canning, dehydration, and preservatives on the vitamin content of fruits and vegetables.

SIR BENJAMIN WARD RICHARDSON

In exhibiting a flagon from Sir Benjamin Ward Richardson's wine cellar at the Section of the History of Medicine of the Royal Society of Medicine on December 2nd, Dr. J. D. Rolleston said that his object was to put an end to a legend connected with Richardson, who died in 1896, and was at once an eminent consulting physician, sanitary reformer, and antiquarian. Although his work and even his name are unknown to a large proportion of the medical profession to-day, his memory, according to Dr. Rolleston, is still kept alive by those interested in such apparently heterogeneous subjects as the alcohol problem, in the scientific investigation of which he was a pioneer, the establishment of model abattoirs and medical biography. Among some of the older members of the profession, including several of Richardson's successors in the chair of the Medical Society of London, the legend has long been current that Richardson, with the fanatical zeal of a teetotaler, had poured down the sink the contents of a priceless wine cellar which had been left him by the celebrated naturalist and antiquarian, Sir Walter Trevelyan, to be applied for scientific purposes. The contents of the cellar, as Richardson relates in *Macmillan's Magazine* of January, 1880, consisted of twenty or twenty-one specimens of wine, spirits, and beer. Very many bottles were half empty, and their corks destroyed, on their delivery to Richardson, but about sixty dozen were in a good state of preservation. Richardson was much embarrassed by the gift, though he had no lack of suggestions as to how he should dispose of it. Nothing however was done, and the bottles, with their contents remained intact in the possession of Richardson's family who last July sent a large consignment to the late Professor W. E. Dixon at the Pharmacological Laboratory at Cambridge, where they still remain, Dixon's untimely death having taken place before an examination of the contents of the bottles could be made. The flagon exhibited by Dr. Rolleston was estimated by the authorities of the Victoria and Albert Museum to date from about 1820 and to be of Austrian or Bohemian origin. According to Dr. J. E. McCartney its contents consisted of 140 c.cm. of muddy dark-brown fluid,

which had probably been a full rich wine with a fairly high alcoholic strength, such as a good Burgundy. Owing to a defective cork, however, evaporation had taken place, and the alcohol had disappeared, either from evaporation or conversion into esters.

RADIUM IN MALIGNANT DISEASE

In a recently issued publication of the Medical Research Council,[1] a comprehensive account is given of the results of radium research in the treatment of cancer and other malignant conditions during 1930. This report, the ninth of its kind, summarizes the work of the Council's thirteen research centres, and takes up the story at the point reached a year ago. Before considering the results obtained from individual centres, the report opens with a brief review of the present position of radium in relation to cancer therapy. The probability of success by this method of treatment depends, as might be expected, on the site of the disease and the early or late manifestation of the growth. At the present moment the breast, cervix uteri, and buccal cavity offer the most promising fields for radium therapy. While in rectal cancer little progress has been made with treatment solely by radium, cases are reported in which advanced growths have been rendered inactive, mobile, and therefore operable as a result of initial radium treatment. The problem of the oesophagus, nevertheless, remains unsolved. The general impression gained is that while radium has a recognized place in the treatment of cancer, its exponents have to rely to a large extent on the selective action of the radiation used. Up to the present no method has been discovered by which malignant cells can be made more radio-sensitive, if we except variations in the time factor. Any successful step in this direction would have wide-felt effects. When due allowance is made for the technical difficulties of treating malignant growths, there seems to be, normally, a considerable range of sensitiveness to radiation among the many varieties of cancer cells. Only further research can show what the expectations in radium therapy may be.

SCIENTIFIC AND TECHNICAL ABSTRACTS

A scientific abstracting service was recently held at the Imperial College of Science and Technology at the invitation of Mr. H. T. Tizard, President of the Association of Special Libraries and Information Bureaux. The object of the meeting was to exchange experience and to discuss methods, not with a view to advocating standardization, but in order to produce a body of information which could be utilized to mutual advantage. The conference unanimously approved of ascertaining the methods employed by societies and industrial undertakings for collecting and reviewing foreign publications. A small committee was appointed to issue a questionary to abstracting organizations and information bureaux, and to summarize the replies. One of the main objects is to try to provide a more complete and prompt review of foreign scientific and technical publications, especially in the less understood languages, such as Russian and Japanese. The committee will attempt to indicate precisely what methods have been found successful or ineffective, and to analyse the collected experience and opinions. It is hoped that all firms and societies which maintain such organizations will help to promote the efficiency of scientific abstracting in general by taking part in the survey. Copies of the questionary may be obtained from Mr. S. S. Bullock, secretary of the Association of Special Libraries and Information Bureaux, 16, Russell Square, London, W.C.1. Replies should, if possible, be received not later than the end of the year.

RESEARCH DEFENCE SOCIETY

Among his many activities the late Lord Knutsford was chairman of the Research Defence Society, a national society of men and women united to promote the health and well-being of the community by bringing about a better understanding of the value of medical and scientific research. To find a successor to Lord Knutsford was no easy task, but the society announces now that the Hon. Sir Arthur Stanley, chairman of the Executive Committee of the British Red Cross Society, and treasurer of St. Thomas's Hospital, has accepted the office. Lord Knutsford had been chairman since the foundation of the society in 1908, and during his term of office he rendered signal service to medical progress by his ardent support of medical research in our hospitals and universities, and, moreover, by his insistence that such work should not be hindered. In Sir Arthur Stanley the Research Defence Society has again secured the services of a man whose life is devoted to the cause of suffering humanity. The society also announces that Professor A. V. Hill, F.R.S., has been appointed vice-chairman, which office has not been filled since the death, in 1926, of Stephen Paget, F.R.C.S., the founder of the society.

POSTURE IN YOUTH

The importance of posture as a sign of correct or faulty muscular balance and tonic action has been long insisted upon by Goldthwait and others in America, and by Dr. M. Forrester-Brown in this country. The lack of a guide to school teachers and those in charge of cripples' clinics in the teaching of exercises intended to develop and strengthen the faulty muscles and restore tone, has been for some time felt. Miss L. S. Rolleston and Lieut.-Colonel W. K. Steele, R.A.M.C., have compiled a very short and simple guide for the use of the Devizes Orthopaedic Clinic.[1] To this Dr. Forrester-Brown has written a foreword in commendation. The chief points aimed at in the exercises are: to reduce exaggerated curves of the spine; to strengthen the abdominal muscles; to develop the capacity of the chest; and to teach the fullest type of breathing. This guide, with its many illustrations, should certainly help teachers to attain the desired ends.

An editorial paragraph in the *Canadian Medical Association Journal* congratulates Professor W. Harvey Smith on receiving the honorary degree of LL.D. from McGill University at its last quinquennial celebration. All members of the British Medical Association who took part in the Annual Meeting at Winnipeg last year under his presidency will be pleased to hear of this honour conferred on Professor Harvey Smith.

Nova et Vetera

AN ELIZABETHAN MEDICAL ADVERTISEMENT

A few really rare medical books may arouse the collecting instincts of connoisseurs in London within the next few days. Perhaps the most desirable is the 'Liber Pandectarum Medicinæ," by Matthaeus Silvaticus, printed in folio at Strasbourg by an anonymous printer in the fifteenth century, bound in contemporary pigskin over wooden boards, with the original iron staple to the lower cover and four links of chain. This is to be sold at Sotheby's on December 14th. In the same sale are R. Boyle's Apparatus ad Historiam Naturalem Sanguinis Humani, 1684, and "Medici Antiqui Omnes, qui Latinis libris diversorum morborum genera et remedia persecuti sunt, a folio of 1547, as well as two or three others of lesser interest. The next following sale, beginning December 17th, contains a Basel issue of 1526 of Hippocrates' "Cor Medicorum Omnium longe principis", a Paris edition of Ambroise Paré's works, dated 1582, a translation, by Culpeper, of Riolanus's Guide to Physick and Chyrurgery, 1657, as well as two or three more original works by this translator, a Galen of 1551, Sir Thomas Elyot's "Castel of Helth," London, 1541 (not the first edition, of course), Philip Barrough's "Method of Physick,' 1596, and John Banister's "Needefull, new, and necessarie Treatise of Chyrurgerie," in the original vellum, 1575.

The foregoing are all for sale by public auction, a few more may be mentioned which are now on sale at W. H. Robinson's bookshop in Pall Mall. Foremost, a copy of the 'Physicorum Elementorum" of Carolus Bovillus, published at Paris in 1512, which contains a manuscript memorandum, bound in as a flyleaf, made about 1575 by a travelling Elizabethan physician and thought to be a notice to be given out by the town crier on the doctor's arrival in each town of his itinerary. This advertisement runs as follows:

> Whereas yt hathe bene reported by certaine maleticus persones that ther ys certaine phesesyons and chururgins and none of them good Then therfor ar to lett all men understand for my dyscharge that occacon doth serve that I must depart from this towne and yf ther be anye man or woman within this town of Richmond or Richmondshire or Newcastell where I remayned last for the space of xviij wekes and now here for the space of ij monthes and odde dayes that if I haue in the places aboutesaid taken anye money of anye person and not performed my convenaunt or discharged my cure accordinghe that they come now to my ost house at Willm Atkinson's And ther I am redie for everye grote so receyved to restore yt duble Least they have occacon to report the lyke by me after my departure Written this xxiij ot October by me Walter Doctor and chyrurgion and practiser in phesycke

In the same firm's catalogue are Walter Bruel's "Praxis Medicinæ," 1632, with the rare leaf at the end giving the apothecaries' weights, Sir John Flover's "Treatise of the Asthma,' 1726, and a number of medical tracts on various subjects, published in the eighteenth century. The Bovillus, which is not in the Bibliotheca Osleriana, is priced at £36.

Another firm, Messrs. Hodgson of Chancery Lane, are selling at auction, on December 11th, the library of Dr. L. W. Sambon, which contains many medical rarities. The most important is a "Hortus Sanitatis," printed at Strasbourg in 1497 by J. Preuss, a clean copy, but slightly worm holed. Others of note in this collection are Ambroise Paré's "Workes," first English edition, 1634; Valverde's 'Anatomy,' 1586, Fabricius's "Anatomy, 1625, Vesalius's "Anatomy," 1642, Durante's "Il Tesoro della Sanita," 1586, another, hitherto regarded as the first edition, 1588, A. T., "A Rich Storehouse, or Treasurie for the Diseased," 1607 (rare), Rueff, "De Conceptu et Generatione Hominis," 1554, and many others.

ANNUAL CONGRESS OF RADIOLOGY

The annual congress of the British Institute of Radiology was held at the Central Hall, Westminster, on December 2nd, 3rd, and 4th. After the official opening by Lord Rutherford, the fifteenth Silvanus Thompson Memorial Lecture was delivered by Sir James Jeans, in the form of a fascinating description of modern theories of radiation. On the following day the twelfth Mackenzie Davidson Memorial Lecture was delivered by Professor Hans Holfelder, who entered upon a comparison of medical, surgical, and radiological conceptions in relation to the treatment of disease. Successive mornings were devoted to a series of papers on the physical side of radiology, and to two medical discussions, which are reported below. An exhibition of apparatus and materials, to which eighteen firms contributed, was associated with the congress.

PRESIDENTIAL ADDRESS

Dr. A. E. BARCLAY, in his presidential address gave a history of the Institute and of its forerunner, the Röntgen Society, and went on to discuss domestic affairs. One looked back, he said, with increasing respect to the early days, when, in the face of inertia and discouragement, the early workers struggled to lift radiology from its humble beginnings. It was their self-sacrificing work which had built up this science and given it the standing it now enjoyed. The Institute was what its members had made it, and it was to the young men on both the medical and physical sides, that they looked to take up the work that began to weary the shoulders of those who had given of their best during the last quarter of a century. Some false and damaging remarks had been lately made about the Institute and he desired to say that it was not, never had been and never would be, financed or controlled in any way by the *x* ray or any other industry. Approximately 80 per cent. of its members were practising radiologists. Of the remainder, a number were physicists engaged in laboratories and in industry, together with a handful of technical assistants in *x* ray departments. He suggested that the council should consider the formation of sections interested in different aspects of radiology and having the power of ordering their own affairs. Without a forward policy he saw the Institute crumbling.

THE RADIOLOGICAL CONCEPTION OF DISEASE

The Mackenzie Davidson Lecture was delivered by Dr. HANS HOLFELDER of Frankfort. At first he said the history of Roentgen and Curie therapy had followed only surgical conceptions of disease; medical conceptions coming later. Radiotherapy, originally created as an accessory method of surgery, had become now an autonomous therapeutic procedure differing in very characteristic features from surgery as well as from internal medicine. The careful planning out and application of the *x* ray beam was one of the supreme duties of the modern radiologist, and conditioned the result of the therapy just as the exact wielding of the knife determined the result of the surgical operation. But it had been proved to be wrong to tie up radiotherapy so very closely with surgical conceptions. Laboratory research had discovered that one could never kill at once and with one carcinoma dose, all the different cell of a malignant tumour, on account of the differing sensitivity of

such cells. It was now known that the toleration dose was increased up to a well-determined degree by splitting up the whole amount of the radiation into a number of small fractioned doses. Thus, the fixed one-day method of treatment was abandoned for a more flexible distribution of treatment over days or weeks—a more troublesome and expensive method, but one more efficient and successful in its results. Radiotherapy was following in the line, not of surgical conceptions, but of those of internal medicine. Though there was not yet agreement as to which method of fractioning the doses was most efficient, it was clearly proved that the results in malignant conditions were considerably better with any of the "long-time treatment" methods than with one-day treatment. Radiotherapy, said the lecturer in conclusion, had become essentially a clinical method, and it urgently required clinical facilities. There were no qualitative differences between *x* rays and radium in regard to biological effect, and the two agents could thus supplement one another very usefully. He believed that the future of radiotherapy belonged mostly to *x* rays, but that in some regions radium should come into combination. For all these reasons he thought it necessary that radiotherapy should be developed, like surgery and internal medicine, into a clinical province, and that in every hospital there should be an autonomous radiotherapeutic clinic, enjoying the same rights as the others in the hospital.

RADIATION TREATMENT OF LEUKAEMIA

Sir THOMAS HORDER, opening the discussion on this subject, said that some form of radiation might be regarded as the most helpful form of treatment in leukaemia. The essential pathology of leukaemia remained elusive. There were two hypotheses in particular: one that the leukaemic state was a reaction to some infective process, and the other that the essence of the disease was neoplastic, though for either of these hypotheses it was rather difficult to find convincing evidence. They were both of some importance in view of the aim of radiation, for if there was a neoplasm certain rules of guidance, derived from the irradiation of known neoplastic areas, could be taken. How did radiation produce its effects in leukaemia? This question, again, must be left open. His own impression was in favour of an indirect, rather than a direct, mechanism. Was the effect of radiation merely symptomatic or to be regarded as curative? He believed it to be symptomatic. He thought it was agreed that if life was prolonged in leukaemia as a result of radiation treatment, it was not prolonged by very much—say, by one-fifth or one-sixth—of the expected duration. Nevertheless, the state of comfort of the patient during this period was considerably increased by careful and well-planned radiation. Leukaemia was controlled, but not cured. As to the aim in radiation treatment, he thought this should not be to bring the white-cell count back to normal, but rather to bring the haemoglobin and red cells to a normal standard—that is, to dispel the associated anaemia and to improve nutrition and general tone. There was a temptation to take the criterion of the blood count too mechanically instead of paying regard to the general state of the patient. The aim should be to improve the patient's general condition as indicated by his own feelings, by a rise in his general state, and improvement of weight if this had been lost. That was better than trying to produce what might be regarded as an ideal leucocyte count. He was rather dubious about a re-treatment at the first sign of some change in the patient; *x* rays should rather be kept in reserve. Certain general features in the patient were contraindications; these included pyrexia, myocardial weakness, renal insufficiency, and haemorrhages. Acute lymphatic leukaemia, which was probably a different disease from leukaemia, was not good material for radiation treatment unless there happened to be some pressure by a particular group of glands, as, for example, massive glands in the neck, or mediastinum. With regard to the relative value of radiation in different parts of the body, once the spleen had become hard from irradiation there was no chance of benefit from further *x* rays. It might be useful to follow the plan of irradiating the thorax (the ribs, scapula, and sternum), as they were rich in blood forming marrow. No doubt the relative values of surface application of radium and irradiation by *x* rays would be discussed.

Dr. N. S. FINZI said that probably cases of leukaemia were underdosed. One reason for this was that it was quite easy to kill a leukaemic patient with *x* rays, especially when it was an acute case, if too large a dose were given in too short a time. There was also a tendency to pay too much attention to the white cells and too little to the red cells and haemoglobin. Dr. Finzi gave a table of acute and chronic cases treated between 1920 and 1927. (He did not include cases of later date because many of these were still living.) It appeared from this table that the average period of survival after the first radiation treatment was one year and eleven months in myelocytic leukaemia, and one and a half years in cases of the lymphatic type. It happened in most cases that on repetition of the treatment larger and larger doses were required to obtain a response, and that in the terminal stages there might be a failure to respond at all. The best results had been obtained when fairly large doses were given eventually, though the initial doses might have been small.

Dr. A. PINEY described some cases treated by irradiation of the long bones and of the spleen. By this means the patients had been kept free from clinical relapses, and rendered able to continue their work—in some cases hard work—for two years or more. In the radiation of cases of leukaemia, the full effect was not obtained right away. The white cells dropped and continued to drop for weeks afterwards, so that it was necessary to cease the radiation treatment before the white cells were reduced too low. He did not believe that the white-cell count or the red-cell count of the peripheral blood was a definite indication of the state of the bone marrow.

Dr. J. H. DOUGLAS WEBSTER agreed with Sir Thomas Horder that a good deal of the effect of radiation was indirect. The more dramatic changes were shown in the myelocytic type of leukaemia, but the end-results in the lymphatic type were better. Dr. Webster described a certain technique of radium treatment, and also discussed different methods of *x*-ray application. He agreed with Sir Thomas Horder that radiation treatment should be held in reserve (not used too prodigally) for definite symptoms.

LIPIODOL IN DIAGNOSIS OF INTRATHORACIC DISEASE

Dr. L. S. T. BURRELL, in opening a discussion on this subject, said that the most obvious indication for the use of lipiodol was bronchiectasis. Its use here was to assist in treatment. The treatment of bronchiectasis depended very largely upon whether the disease was unilateral or bilateral. He had frequently seen cases with obvious signs of bronchiectasis on one side, but only by the use of lipiodol had he discovered considerable bronchiectatic dilatation on the other side. Before urging a surgical operation of any magnitude, therefore, it was essential to have an *x*-ray examination after using lipiodol. Again, it was difficult or impossible clinically to determine the extent of the bronchiectasis. As treatment depended very largely upon this, lipiodol was useful for the purpose of diagnosis. It was not until lipiodol was introduced that it was recognized that a certain proportion of cases of unexplained haemoptysis were really bronchiectatic. Abscess of the lung might be another indication, if

he had not had very much help from lipiodol in such cases. Lipiodol did not enter the abscess, but it might occasionally be useful in assisting to locate it. In carcinoma of the bronchus, too, lipiodol would often suggest the diagnosis. He had also seen cases of pyo-pneumothorax, or spontaneous pneumothorax, where lipiodol had been used to try and locate the site of the perforation and discover whether the perforation was still open. As for contraindications, in pulmonary tuberculosis lipiodol did sometimes cause an exacerbation of the disease. He had read that it produced haemoptysis in cases of tuberculosis, but possibly the occurrence was a coincidence. What was sometimes found with lipiodol was that the patient got iodine poisoning. There were also other cases of discomfort, and altogether lipiodol should not be used indiscriminately.

Dr. STANLEY MELVILLE, speaking with regard to bronchiectasis, said that they had been told in the past—and most of them had believed it—that the chief factor in the causation of bronchiectasis was chronic cough, which produced such increase in the intrathoracic pressure as to dilate the bronchi. There was very little in support of such a theory. Not enough was thought about the physics of intrathoracic pressure. The most interesting thing in connexion with bronchiectasis was the occurrence of haemoptysis; frequently a recurrent haemoptysis was the only evidence of severe bronchiectasis. The initial lesion from the pathological point of view was invariably a definite ulceration in the bronchial wall itself. Another matter with regard to which they had got a little adrift was the fact that all bronchiectasis was regarded as being a fibrotic condition. There was very little fibrosis as a general rule.

Dr. JAMES MAXWELL found that, on the whole, the cases in which he used lipiodol were getting fewer every year. As to methods of administration, in his view the nasal method was the one of choice. One point about lipiodol should be stressed—namely, the necessity of making sure, before putting lipiodol in the chest, that the patient was not sensitive to iodine. Dr. DUNCAN WHITE recommended an intra-oral form of injection, and said that fully 80 per cent. of the cases could be examined satisfactorily by this method. The whole success of it depended upon the control of the tongue. Dr. W. J. FENTON dealt with the spray method of anaesthetizing the larynx, and the use of a laryngeal mirror, showing an arrangement which he had devised for the purpose. Dr. J. V. SPARKS showed a number of lantern slides illustrating cases in which the crico-thyroid method of injection had been followed. Dr. ALEX. ORLEY spoke in favour of the nasal method.

Finally, Dr. PETER KERLEY dealt with the subject of bronchiectasis in children. He said that this was not by any means a simple diagnostic problem, which the textbooks led one to believe. Of sixty proved cases of bronchiectasis in children seen at the Royal Chest Hospital, thirty-two lacked the characteristic symptoms, and were first diagnosed as chronic bronchitis or post-pneumonic fibrosis. The only symptoms were cough and coarse rales at the bases, this despite the fact that many of the patients had lobar collapse. In the Royal Chest Hospital lipiodol injections had taught them three interesting facts: (1) increased translucency due to compensatory emphysema was a persistent accompaniment of infantile bronchiectasis, and in not a single case was there loss of translucency around the bronchiectatic areas; (2) the diaphragmatic movements in infantile bronchiectasis were usually better than those with post-pneumonic fibrosis and chronic bronchitis; (3) when a collapsed lobe was present there was invariably a congenital basis for the bronchiectatic dilatation. The lobe was collapsed before it was bronchiectatic, and might be bronchiectatic for a considerable time before it became infected.

Scotland

Royal Infirmary, Edinburgh

At the thirteenth annual meeting of the League of Subscribers to the Royal Infirmary of Edinburgh, held on November 26th, a statement regarding the year's work was made by Dr. John Orr, of the board of managers of the institution. Referring to the question of payment for treatment in the infirmary, the speaker said that a clause in a provisional order promoted by the town council before Parliament, designed to give the managers of the infirmary powers to institute paying wards, had been withdrawn. According to the present constitution the infirmary was unable to make a charge upon any patients admitted; but the Maternity Hospital, which was soon to be incorporated in the infirmary, had a proportion of paying beds, and it would be necessary to obtain permissive powers to institute charges for treatment when the responsibilities of the Maternity Hospital were taken over. The waiting list, which stood at 2,900, indicated that people appreciated the services which could be given, and were willing to wait for a certain time in order to get the benefits of the institution. There was always room, however, for every person who required immediate attention or operation; every primary accident case, every urgent medical case, and every case of cancer was provided for at once. Last year the number of occupied beds had been 973, as contrasted with the 6 beds available when the institution was opened two hundred years ago; 19,184 in-patients were treated during the year and 64,081 out-patients. A matter which called for investigation was the cost to the infirmary of treatment in cases of motor accidents. In the past year 396 such cases had been treated at a cost to the infirmary of £3,360, and for these the infirmary had recovered only £234. A report from the League of Subscribers showed that, as a result of a general survey of the Edinburgh district, there were few large works or business establishments which did not contribute in some form to the league. There were numerous small places of business, with small staffs, which covered a large section of the community, and the league was endeavouring to extend its operations to these persons. With regard to contributory schemes operating in English hospitals, it was suggested that the practice prevailing among English employers, who contribute an agreed percentage of that subscribed by the employees—sometimes as high as 25 or 33 per cent.—might be adopted. This was more generous support than prevailed among Scottish employers towards hospital finance. The league had collected for the financial year ending September 30th, 1931, a total sum of £21,867. Of this sum, £16,027 had been subscribed by the 1,160 groups of subscribers in the city, and 388 groups in country districts had collected £5,839. Although the sum contributed had shown an advance of £204 on the contributions for the previous year, a large number of groups had collected a smaller amount, or had suspended payment altogether in consequence of unemployment. Of the subscribing groups the largest was that of employees of the L.N.E.R. Company, whose contributions amounted to £1,074. Among the provincial towns served by the infirmary the outstanding contributions were: from Kirkcaldy, £687; Musselburgh, £414; Galashiels, £401; and Hawick, £348. During the thirteen years of the league's existence there had been handed over towards the maintenance of the infirmary an aggregate sum of £245,525.

A meeting of the General Committee for the Royal Infirmary Bicentenary Extension Appeal Fund was held in the City Chambers on November 25th. Lord Provost Sir Thomas B. Whitson presided, and said that towards the

desired sum of £500,000 the amount at present subscribed was £222,000. It was reported that a general appeal had been issued in October of last year, and a further appeal had been sent to every medical graduate of Edinburgh University, in reply to which contributions had been received from almost every part of the world.

Glasgow District Nursing Association

At the annual meeting of the Glasgow District Nursing Association, held in Glasgow on November 23rd, Sir Archibald Campbell, Bt., of Succoth, mentioned that he had offered to transfer Garscube Cottage Hospital to the association for the nominal price of £500, on the condition that the building should be used solely as a residence for nurses or such other charitable purpose. The hospital was erected in 1876 by the late Lady Campbell, his cousin, with the intention of using it as a convalescent home. At the time of the South African war it was used for sick and wounded soldiers considered to be incurable, and it was used again as a war hospital from 1914 to 1918. For some years it had been employed by the Public Health Department of Glasgow Corporation as a convalescent maternity hospital, and it was now proposed to transfer the hospital to the Glasgow District Nursing Association at Whit Sunday, 1932. Dr. A. S. M. Macgregor, medical officer of health for Glasgow, said that he knew of no other service which conducted such widespread operations as the District Nursing Association on so small an annual sum as £12,000. The association was a valuable ally to the city hospital, and ought to be expanded. The annual report showed that during the year 9,463 cases had been visited, and that in all 219,503 visits had been paid. The ordinary income for the year, excluding £500 from Bellahouston Bequest Fund for the purchase of Garscube Cottage Hospital, had amounted to £12,924, and the expenditure to £12,252.

Foot Clinic in Glasgow

The Incorporated Society of Chiropodists in Glasgow has established the Glasgow and West of Scotland Foot Hospital at Windsor Terrace, Glasgow, for the provision of free foot treatment for the poorer and working-class community in the West of Scotland. This movement was due to the success which has been attained for some years past by the foot clinic in Edinburgh. The Glasgow Foot Hospital consists of an eight-apartment dwelling-house, in three floors, which has been converted for the purpose. The clinic will be open on Monday and Wednesday of each week, but it is anticipated that, when it becomes better known, a morning and evening service will be necessary. The voluntary staff consists of ten male and six female chiropodists. The initial expenses of opening the institution have practically been covered, and it is expected that within a short time the small remaining deficit will be met and the work of the hospital rapidly developed.

Edinburgh Mothercraft Club

A club has recently been formed in Edinburgh, under the presidency of the Countess of Rosebery, with the object of helping mothers in the care of children under 5 years of age. This organization aims at doing for the more well-to-do mothers what child welfare centres do for the poorer classes. A clinic in charge of a registered nurse will be held once weekly at Castle Terrace, Edinburgh, for the benefit of mothers desiring help. Advice will be given to expectant mothers in regard to the bringing up of children, feeding, etc., and lectures and practical demonstrations will be held. Dr. James Young is the chairman of the committee of management, which includes several medical men and others who take a special interest in the objects for which the club exists.

Ireland

Irish Sweepstakes and English Hospitals

In his reply to a letter from Irishmen in London suggesting that English hospitals might benefit from the next Irish sweepstake, the Lord Mayor of Dublin points out that the Act of the Dail, authorizing the sweepstakes, specifically confines their benefits to Irish hospitals. To amend the Act to include English hospitals might expose the Dail to a charge of interference in English legislation. If, however, any English hospital applied for a voluntary donation, or made it clear in some other way that an unconditional gift would be acceptable, the position, in his view, would be altered. It appears that in a subsequent letter the Lord Mayor states he desires to make it clear that in suggesting a voluntary contribution towards the English hospitals he did not intend to suggest that the Hospitals Trust should make such a grant. His intention was that, in view of the splendid way that the British public had come to the assistance of the Irish hospitals and helped to make a success of the "sweep," the Irish public might, in return, help any English hospital which was in difficulties by a voluntary contribution. Sir William Taylor, in the course of an interview, stated that English hospitals could not benefit from the sweep stakes. Such a suggestion was quite contrary to the Act which legalized them. If, he pointed out, the British Parliament authorized sweepstakes for the hospitals, it would be quite within the rights of the Irish Hospitals Trust to arrange with the English authorities to have two sweepstakes for each country at times when they would not clash. The Irish Hospitals Trust could even undertake to run them, allocating the proceeds from two sweepstakes to the English hospitals and the proceeds from the remaining two to the Irish hospitals. Sir William pointed out that the Irish hospitals received the money for their own benefit, and under the Act they could not use it for any other purpose.

Poor Law Reform in Northern Ireland

The main proposals for the reform of public services in Northern Ireland, as set forth in a circular issued by the Government, are as follows: boards of guardians (except the Belfast board) to be abolished, and their duties vested in new committees for areas larger than the present unions; regional homes to be substituted for workhouses, and to be administered by a special committee of representatives of certain urban and rural districts, the admission of inmates to rest with the councils of the districts concerned, and the expense of the administration of the home to be chargeable to the various districts; rural and urban councils to be responsible for outdoor relief, which is to be administered on a purely district basis; each county to prepare a scheme involving the establishment of one or more district or regional hospitals serving a specific number of rural and urban districts in that county, the hospitals to be administered by special medical committees appointed by the councils of the districts concerned, and the costs of the hospitals to be borne in a manner similar to the arrangement proposed for the regional homes. It is proposed to link up the hospital system with the medical relief system by making the medical committees responsible for medical relief in the homes of the sick poor and in clinics in the regions concerned; county councils to administer public health services, but urban and district councils to retain their local executive functions; county councils to have power compulsorily to remove to hospital persons suffering from tuberculosis who are likely to infect others. Each county council will be required to appoint a county

medical officer of health, with assistant officers of health for certain areas, this new service to be substituted for the existing disjointed system under which dispensary medical officers automatically become medical officers of health for rural and urban areas at nominal salaries It is suggested that tuberculosis medical officers and school inspection medical officers should be included in the service, and that county councils might co ordinate and strengthen the veterinary staffs, and so relieve the rural and urban councils of the cost of the part time officers

England and Wales

London School of Medicine for Women

The annual dinner of the London (Royal Free Hospital) School of Medicine for Women was held at the Savoy Hotel on December 3rd, under the presidency of Lord Riddell The number of members and guests present was 430, which, it is understood, constitutes a record attendance at this function The principal toast, that of "The School and Hospital," was proposed by Lady Simson (Miss Lena Ashwell), who evoked in her speech memories of the fight for women's suffrage, and paid a tribute to medical women of the past, notably Miss Jex Blake and Mrs Garrett Anderson, for their adventurous spirit, which had resulted in opening up the profession to women Lady Simson invited the company to wish all the women now working in the school and hospital the courage, enthusiasm, and tenacity of purpose of those pioneers who had made it possible for these their daughters to enter the great profession of medicine Lord Riddell, in responding, mentioned that during the last five years the hospital had raised £500,000 Shortly after a recent wireless appeal which he had made, a lady had furnished a cheque for £18,000, the amount of the overdraft at that time, the only condition being that her identity should not be disclosed The amount of the present overdraft was £40,000, and he hoped that someone present would emulate, if only in part, the example of that very noble lady He welcomed the appointment of Miss Bolton, M D , who had succeeded Lady Barrett as dean of the school , her judicial mind should prove a tower of strength The thanks of the school must also be tendered to Sir Alan Anderson, Sir Francis Dyke Acland, and Miss Brooks, the warden Dr Haldin Davis, in welcoming the guests, coupled with the toast the name of Miss E. M Delafield, the novelist, and also that of Dr H H Bashford, another charming writer But the "surprise packet ' of the evening, he said, was that Miss Peggy Salaman, the heroine of the recent flight to the Cape, had dropped out of the skies as their guest also He expressed admiration for the pluck, courage, skill, and organization exhibited during her wonderful journey Miss Delafield, in responding, mentioned some of the tribulations of a novelist, including the indignation of a reader who, referring to what the author believed to be an entirely new character, said, "Where did you meet my Aunt Jane, and how dare you put her in your book?" Dr Bashford also thanked the school for its hospitality, and made some amusing remarks on the psychology of early childhood Miss Peggy Salaman, who was greeted with warm applause, described the success of her flight as having been due to good luck and weather Dame Louise McIlroy expressed the delight of the company at seeing the chairman, Lord Riddell, so fully recovered from his recent illness In proposing his health, she said that the names of Dr Carr and Dr Burrell ought to be coupled with the toast for their share in promoting his recovery The hospital lived in the reflected glory of its president's achievements In addition to possessing an attractive personality, Lord Riddell occupied great positions in the newspaper world and the world of public affairs. The reputation of the hospital was always safe in his hands, and they owed much to his wisdom and generosity The toast was given musical honours, and Lord Riddell briefly replied After the conclusion of the speech-making a large proportion of the company remained for a dance.

Disease and the Public Abattoir

In the tenth Benjamin Ward Richardson Memorial Lecture, delivered to the Model Abattoir Society, in London, on November 25th, Mr Hal Williams, designer of the new abattoir for the Sheffield Corporation, paid tribute to the aims and ideals of Sir B W Richardson, the founder of the society, and pointed out that the public health and economic aspects of a public abattoir were of the first importance Touching on one much debated question, he said that far more cruelty took place in the mishandling of the animals than in the act of dispatch, and the old-fashioned design of many existing public abattoirs left the slaughtermen with no alternative Experience had shown that wherever slaughter was concentrated in one place in which a proper system of meat inspection existed, there was an extraordinary increase in the amount of meat condemned as diseased and unfit for human food After the opening of the Sheffield Corporation abattoir the increase of diseased meat was approximately 80 per cent The only possible inference was that that increase represented the amount of diseased meat that had previously been eaten—in most cases by the poorest of the population It had been proved beyond question that the consumption of diseased meat was responsible for disease, and its effect on the national health and physique was devastating A sound and healthy meat supply could only be obtained by rigid and thorough inspection, and this was only possible when private slaughterhouses were abolished and the slaughter of animals was concentrated in an abattoir designed for that purpose In this direction, and in the support of veterinary training, we were far behind the leading Continental nations, where all meat was by law, killed in public abattoirs The speaker advocated regional abattoirs, which would enable proper inspection to be carried out, assist the movement for the grading and marking of meat conducted by the Ministry of Agriculture, and not interfere with any of the butcher's legitimate opportunities for making a profit by the exercise of his judgement The value of this system had been thoroughly proved at Adelaide, Australia, and had been recommended by a commission of investigation appointed by the Queensland Government in 1928.

Voluntary Patients at London Mental Hospitals

A report presented to the London County Council shows that the number of voluntary admissions to its ten mental hospitals during the three months ending September 30th was 38, and the number of departures 21 A total of 63 patients (36 males and 27 females) were in residence on the date mentioned The number of patients, all voluntary admitted to Maudsley Hospital (which is not included among the county mental hospitals) during the same quarter was 140 the number departing was 145, and the number of deaths 4 The patients in residence at Maudsley on September 30th numbered 177 (73 males and 104 females In addition the number of patients receiving treatment in the out patient department at Maudsley during the quarter was 1,171 (386 men, 590 women, and 195 children

Correspondence

"THE MENTAL DEFECTIVE"

SIR,—I have read with interest and profit Dr. Tredgold's signed review of the above work. It leads me to hope that the net result may be a quickening of professional interest in a national and social problem of protean aspect. Restricted as English practice necessarily is by Acts of Parliament and the definitions contained therein, the resultant outlook on mental deficiency will almost certainly differ from that obtained from a biological survey, or from the practice of countries where such definitions are not in operation. My own experience has been chiefly derived from this wider field. When these several legal and biological jigsaws can be fused into a composite and finished picture the apparent differences of opinion or of interpretation of facts between the reviewer of this book and its authors will be found to be on convergent lines, not on those which never meet.

Dr. Tredgold has correctly enough pointed out several errors, especially on the legal side, which have crept into the book, but, if opportunity arises to remove them, such blemishes will disappear. It remains true, however, that I have myself seen such follies as teaching the names of the Saxon kings to low-grade defectives, and from an extensive knowledge of institutions I know many lay visitors whose knowledge of mental deficiency really is in inverse ratio to their enthusiasm. For them this book was largely written. I fancy Dr. Tredgold would agree with the objective, and should accept the necessary "dogmatism" so essential to successful teaching or preaching. If these be indeed "grave faults," I am entirely unrepentant.

That Dr. Tredgold finds some clinical descriptions to be of little value I can well believe, for they are much better done in his own successful book, and this being so it would have been a futile ploughing of the sands for us to do again what he has better done. On the other hand, from some of his comments my own experience (which I again emphasize has been gained in other fields) leads me to differ. Mental deficiency as it presents itself in the consulting room, and especially as restricted by the Acts of the lawyers, is one thing. As met with in the greater world beyond it is quite another. That the numbers of undeveloped defectives in the nearly 200 million peoples of Great Britain and the United States may be nearer the biological 15 or 20 per cent. than the statutory 8 per thousand is not nearly so devoid of evidence as Dr. Tredgold would have us believe. Personally, I should hope that he is right and I am wrong, but I doubt it. I found the Middle West of America a perplexing and disturbing problem, as I also do many of our own C 3 folk; but then I do not view these through the rosy spectacles provided so generously by the law, so there is ample room for differences of opinion. Nor do I agree with Dr. Tredgold that we must necessarily follow a division of the amentias into primary and secondary, nor that we must equally slavishly agree with these unsatisfactory distinctions for all time. Again, experience has led me, and is increasingly doing so, to a profound disbelief in the existence of "types" of mental defectives. I can see little or no difference between the *imbecility* of the mongolian imbecile and that of any other imbecile, though why the former should be accompanied by some very definite *physical* characteristics is another, and to me inexplicable and unexplained, problem, unless, indeed, Crookshank be really right in his ethnological theses.

All these are, however, differences of interpretation rather than of fact; and if Dr. Tredgold's review, coming as it does from one of his deservedly great reputation, directs the attention of the profession, not so much to the small book in question, but to the greater problem beyond, I feel sure that both reviewer and authors may rest content, for that, after all, is what we really have at heart.—I am, etc.,

RICHARD J. A. BERRY.

Stoke Park Colony, Stapleton, Bristol, Nov. 30th.

EPIDEMIOLOGICAL REPORTS OF THE LEAGUE OF NATIONS

SIR,—I should be glad if you would give me the opportunity of replying to the reference in Dr. E. W. Goodall's letter in the *Journal* of November 21st relating to the reliability of the figures given in the Monthly Epidemiological Report of the League of Nations.

It is unfortunately inevitable that figures relating to prevalence of particular diseases given in different publications of the Epidemiological Intelligence Series should sometimes materially differ, seeing that they have to be taken from different official publications and returns, which may have been prepared with different objects at different times and from different data. This particularly applies to figures of notified cases given by countries which are in a transition stage in regard to notification.

In the League of Nations' monthly reports the discrepancy between the two tables noted by Dr. Goodall is accounted for by the fact that in one table the figures from the weekly returns of notified cases were given, whilst the second table is taken from the reports of cases in hospital for the whole year. As typhus was not compulsorily notifiable at the date in question the numbers notified were naturally only a very small fraction of the total cases. "Tropical" typhus was only made compulsorily notifiable in the Federated Malay States in 1930. —I am, etc.,

Y. BIRAUD.

League of Nations, Geneva, Dec. 2nd.

MUSCLE SPASMS IN CHRONIC ENCEPHALITIS

SIR,—Dr. Arthur Hall has done valuable service to the study of chronic epidemic encephalitis by devoting a large portion of his recent Schorstein Lecture to the special consideration of the ocular attacks, which are now such familiar features of the disease. But in pondering the ingenious and suggestive theory, which Dr. Hall has done so much to promote, that the various fixations which occur represent dissociated elements in the posture of sleep, one must, I think, recognize that there are still certain difficulties in harmonizing this theory with all the facts. May I mention a difficulty of mine, and illustrate it by a case which is at present under my care?

Those who have watched a group of these patients upon an institutional playing-field are familiar with the sudden access of mobility which enables a youth whose rigid, shuffling pace is about four inches, to swing his arms and shoot an excellent goal when he finds the football at his feet. A counterpart to this dramatic remission of the poverty of movement, to which Dr. Hall refers in his lecture, is a sudden conversion of poverty of movement into absence of movement. A patient who has walked the length of the room swinging his arms will slip one arm half out of the sleeve of his dressing-gown and then become immobile for ten or twenty seconds. During such attacks it is usually possible to detect an increase in muscular rigidity. The subject's own description is that the limbs suddenly refuse to move. Ocular crises frequently accompany these attacks of immobility.

I have three patients at the present time who show "in and out" of ocular attacks all day long. In one of these the attack consists of an *active* spasm of the eyelids, unaccompanied by obvious change

general rigidity Another, however, has the following syndrome, constantly repeated The ocular spasm, or posture, directs the eyes downwards and slightly to one side At the same moment speech is lost (" the words come to my mouth, but I can't get them out "), the neck flexes slightly, with a slightly increased rigidity of the neck muscles, and if one arm be moved back and forth passively before and during the attack, there can be no doubt about an increase of rigidity with the onset of the attack In this case, too, there is usually an active spasm of the eyelids during the crisis

In interpreting spasmodic muscular contractions and postures as " release phenomena " it is difficult to know where to stop, but in view of the type of case illustrated in this patient it is difficult to abandon a conception of the ocular attack as being linked with the other inhibitions of motor function which, together with itself, are frequently linked, by coincidence in time at least, with variations of rigidity It is also difficult to feel quite convinced that all these events can find their explanation along a line of association, or of dissociation, of the function of sleep —I am, etc.,

London, W 1, Nov 24th RANYARD WEST

DEATHS ASSOCIATED WITH ANAESTHESIA

SIR,—Dr Frederick L Hoffman's letter in your issue of November 28th is interesting, but, I am afraid, not illuminating Anaesthetists would wish to know before taking his figures too seriously to heart (1) What is the death rate (under or associated with anaesthesia) per 100,000 *anaesthetics given* in the United States of America and England and Wales? (2) What are the laws governing those whose duty it is to report such cases in the two countries? (3) How far are those laws conscientiously observed? Without answers to these questions no proper conclusions can be arrived at from Dr Hoffman's figures —I am, etc,

London, N W, Dec 1st RAYMOND E APPERLY

ALLERGY AND THE " PROTEOSE "

SIR,—In reply to Dr John Freeman's letter, published in your issue of November 28th, I should like to draw attention to the following points

1 In the isolation of a new substance it is an invariable experience that the original technique used for isolation has to be modified in the light of subsequent experience The *criterion of potency of proteose* does not depend on its quantity, but on its power of reaction with antibodies Whereas a normal person excretes a certain quantity of " proteose " he never so far as I am aware, gives a positive skin test to this substance, neither does its injection cause symptoms

2 Dr Barber will, I believe explain to Dr Freeman the *technique which should be employed to elicit a specific* reaction in the eczema asthma syndrome

3 The case Dr Freeman quotes as giving a negative reaction to ' proteose ' by his technique was used for the experiments in urinary antigens reported to the Royal Society of Medicine (*Proc Roy Soc Med*, Section of Dermatology, July 1931 xxiv 55) In Fig 1 the experiment with " proteose " labelled " *Proteose, Dr F.'s case*," is the identical case which Dr Freeman quotes as giving a negative skin reaction Guinea pig experiments were used in this connexion as they are recognized to be more specific than skin tests

4 In some work in process of publication, Dr Combeare working at the Asthma Clinic, Guy's Hospital, undertook an independent investigation, using a " proteose " isolated from a patient suffering from hay fever-asthma and tried the effect of intradermal tests with this patient's " proteose " on (*a*) pollen sensitive subjects (*b*) asthmatic subjects who were not pollen sensitive, (*c*) normal controls. In this series of approximately 100 cases it was found that 80 per cent of the pollen-sensitive patients gave positive skin tests to the hay fever " *proteose*," whereas *none* of the normal controls did so. Some 20 per cent of the asthmatic patients who were not pollen sensitive gave positive tests It is interesting that some of these patients were clinically hay fever subjects, although they gave negative skin tests to pollen Tracings of all these skin tests were kept, and will be available for inspection by anyone interested as soon as Dr Combeare, who is at present in America, is able to return them

It seems to me that the question of the specificity of the " proteose " is of sufficient importance to justify further investigation, and I should be pleased to arrange a demonstration of the skin tests in which Dr Freeman finds difficulty, if he will be good enough to indicate the time and place that will be suitable for him —I am, etc,

London, W 1, Dec 2nd G. H. ORIEL, M D

ASTHMA STATISTICS

SIR,—Your editorial review of Gram's " Danish asthma statistics " is very interesting, but the age incidence varies so greatly from that found to exist in my own series of cases that one may doubt whether the figures taken from a " sickness insurance organization " give us much idea of the age incidence in Denmark as a whole

Reduced to percentages, Gram finds that in his series of cases asthma started in the first five ten yearly *periods of* life, in the proportions of 12, 13, 24, 23, and 16 per cent. of his patients respectively The age incidence in my own series of 1,000 cases (already published) was totally different—namely, 40 started asthma in the first ten years of life, 12, 15, 13, and 9 in the subsequent decades In a second series of 1,000 cases my figures are 39, 13, 14, 14, and 11 Thus I differ from Gram My finding is that asthma most commonly commences in the first ten years of life

On the question of sensitization his figures agree almost exactly with mine Applying my percentages to the numbers of patients he details to each ten yearly period, I should expect ninety-six of them to give reactions to the dermal tests As a matter of fact he found *ninety-one* to be sensitive to this method Thus the skin reactions, which were at one time so much belittled, again receive confirmation

Probably a series taken from our own national insurance service would be more correctly parallel with Gram's cases, but in neither case would they give the asthma figures for the whole population In short, I see no reason to suspect any difference in the age incidence of asthma in two places so similarly situated as Denmark and England —I am, etc,

London, W 1, Dec 7th FRANK COKE, F R C S

" REAL PAIN "

SIR,—In your report of the Royal Society of Medicine's discussion on nervous dyspepsia (*Journal*, December 5th, p 1035), Dr Robert Hutchison is represented as having said that " the presence of real as distinct from imagined pain might almost be said to negative a diagnosis of nervous dyspepsia Possibly unavoidable condensation of his remarks has eliminated whatever he may have said to define and explain the distinction to which he refers This is unfortunate for it would be interesting to know by what criterion he estimates the reality of pain, dyspeptic or otherwise A patient may be imaginative or mistaken as to the reasons he gives for his pain or as to the organ which he states to be involved on such matters he is not competent to judge But surely what makes pain real is simply painfulness and on that point the patient is the only possible judge Failure

to appreciate this fairly obvious fact must mean that "real" pain will receive real treatment and "imagined" pain will receive imagined treatment. That, indeed, is what only too often happens. The physician is as self-deceived as his patient if he fails to recognize that subjective realities are, in their own way, as "real" as any other sort of reality.—I am, etc.,

Glasgow, Dec. 5th. D. YELLOWLEES.

*** We understand from Dr. Robert Hutchison that what he said was: "The presence of real (or, if you like, 'severe') pain as opposed to mere discomfort may almost be said to negative," etc.

CHILD GUIDANCE CLINICS

SIR,—I have followed this correspondence with interest. I had no intention of taking part in it till I read Dr. E. Rowland Fothergill's letter in your issue of December 5th. That letter contains the surprising suggestion that the work of child guidance should be relegated to the private practitioner.

As far as my own experience goes, most private practitioners are very ready to admit that their knowledge of psychopathology in the child is limited. With adequate study and training many of these could no doubt do a great deal to cope with the simpler maladjustments of childhood. In the absence of such knowledge, and in the severer cases, the child guidance clinic fulfils an important function. I submit that its essence is team work. The psychiatrist does not pretend to have the technical knowledge of the working psychologist, nor yet the leisure in which to visit the homes and collect the family histories which constitute the function of the social worker. But apparently the general practitioner is not only to know more than the psychiatrist, but also to have more time at his disposal.

If the child guidance movement is essentially on wrong lines, and if the work would more properly be done by the private practitioner, I would ask Dr. Fothergill to explain the following points: (1) Sir George Newman, in his 1930 report, devotes five pages to the subject of child guidance clinics without making the suggestion that the proper man to treat the behaviour problems of children is the private practitioner. (2) A large number of private practitioners refer cases to our children's department, and appear to appreciate our efforts. (3) School teachers are increasingly prone to advise parents to take their difficult child to a child guidance clinic. (4) Magistrates of juvenile courts make extensive demands on our resources, but I have still to learn that they would prefer to have a report on the mental status of a juvenile delinquent from a private practitioner.

Dr. Fothergill denounces "a mass treatment system" as "contrary to all the dictates of medicine." Perhaps he is right, but assuredly there is no shred of justification for describing the work of a modern child guidance clinic as "mass treatment." On the contrary, the amount of individual study each child receives is the most complete antithesis of the "mass treatment" to which many an overworked private practitioner is driven in coping with a large panel practice.

I am ready to believe that there are weak spots in the child guidance clinics now available in this country. It is possible that they have been modelled too closely on the American pattern. We hope that such defects will in time be eliminated. Two facts are, however, beyond dispute. The first is that they are doing work which the private practitioner could not hope to do as well, even if he attempted it. The second is that their methods can, in no circumstances, be described as "mass treatment." In controverting these points, Dr. Rowland Fothergill reveals complete ignorance either of the methods of the child guidance clinics or of the requirements of the maladjusted child.—I am, etc.,

December 7th. H. CRICHTON-MILLER, Honorary Director, Tavistock Square Clinic.

CHILD PSYCHOLOGY

SIR,—Our attention has been called to an annotation in the *British Medical Journal* of October 10th, the opening sentences of which are: "It has been a common complaint of Continental and American visitors that there is no provision for the study of medical psychology in London. Especially is this true for those wishing to study child psychology." It is nowhere explained in the article that this complaint is unjustified, being based on misinformation. It is not our place to enumerate the many institutions in London at which some aspect or other of medical psychology is taught; but we wish to say that at the only institution in this country where instruction is given in psycho-analysis—the central theme from which the rest of modern medical psychology radiates—namely, the Institute of Psycho-Analysis, there is a special department in which child analysis is both taught and practised. Further, London is in some important respects the only place, not only in the British Empire, but in the world, where this important instruction is available. Therefore, while we agree with your implied conclusion that the teaching of medical psychology in London still leaves very much to be desired, we should like to point out that there is another side to the picture which is worthy of mention.—We are, etc.,

ERNEST JONES,
Director, London Clinic of Psycho-Analysis.
EDWARD GLOVER,
Assistant-Director, London Clinic of Psycho-Analysis.
SYLVIA PAYNE,
Secretary of the Institute of Psycho-Analysis.

London, W., Dec. 2nd.

EDUCATION IN QUESTIONS OF SEX

SIR,—It is so seldom that the Church visits our province of medicine and makes such a welcome practical contribution toward the solution of a medico-social question that I have been moved to re-read the address delivered at the Eastbourne Meeting of the British Medical Association by the Rev. Wentworth Pym, published in the *Journal* of August 1st. Anyone engaged in mental medicine must be struck with the large percentage of patients with nervous and mental illness whose history discloses that the foundations of derangement were laid during the sheltered period of childhood and adolescence. Canon Pym, however, deals with only a section of the trouble, which he lifts out of its natural setting, and which could, perhaps, be more adequately treated by inclusion in a bigger and more comprehensive survey of the world scheme.

All life, at all levels, is really a struggle to live, and, though civilization brings the necessaries to our doors, the ambition for social success and eminence merely replaces the simple needs by something more specious but equally clamant. The well-meaning parents in their tender love of their offspring shield them from a knowledge of the actualities of life, and unwittingly lead them to unhappiness and destruction by an over-pampering care and worship, resulting in Narcissism and self-omnipotence—an egocentric incapable of dealing with anything it cannot overcome. So is formed the first barrier against discipline and proper parental control and relationship.

Although far removed from primordial life we are nevertheless, the inheritors of every level from the simplest to our own crowning heights in humanity, and are inherently furnished with the means of living in an environment swarming with battling factors, which we should be capable of overcoming, and also adapting ourselves to our surroundings. All life is one vast brigandage the greater absorbing the lesser, but these natural phenomena, seemingly cruel by our human standards should be explained as part of the scheme of the universe, and not hidden from developing youth.

It is reproduction which replenishes this wastage and reveals a unity of purpose which we can observe but neither explain nor understand. Examples of natural forces constantly working can be demonstrated—such as gravity magnetism, polarity, and the affinities of the elements of which our bodies are composed. The school chemistry experiments serve to show the perpetual flux in the inorganic kingdom, also plants flowering seeding and springing up again. To the more advanced youth the ties of companionship, affection, love, and passion may be dwelt on and explained in their setting of romance and tragedy and he may be shown how links can be forged in the mind which survive when passion and love have faded. A background of this kind of abstract texture gives the subject of sex a fitting place as one of the most profound mysteries, and without which life would be poor indeed. Unfortunately the subject is approached too directly, and with insufficient delicacy, or is treated as though it were altogether taboo, producing shock and embarrassment in a matter which can be made beautiful, for there is nothing improper in nature—it is only the mind that makes it. Later on with no apprenticeship to life as it is, and little knowledge of the facts, *the rough and tumble comes as an astonishment* and there is inability to adjust matters, the usual problem of undeserved suffering presents itself and either Job's attitude is taken, or his wife's which is frequently the prelude to a mental home. There is nutritional hunger and sex hunger, and with some who are more highly charged, it is almost as dangerous to renounce the one as the other for there is that insistent inarticulate quest which will assert itself at times for satisfaction and full orbed development of self.

Canon Pym has given most valuable assistance towards handling a very hushed subject, and these humble suggestions are made as a plea for extending and further clothing the subject without in any way clashing with modern Church doctrine or morality. In my experience I have been forcibly led to the opinion that with many people the mere mention of 'sex' envisages the organs of reproduction rather than one of the most wonderful mysteries in creation, and (as stated in the address) it is to the quality of the mind of the educator that we must look for suitable presentation of this interesting and important theme.—I am, etc.,

Armagh Nov. 28th ARTHUR KING, M.D.

THE CREOSOTE ENEMA IN PNEUMONIA

SIR,—In recent papers and lectures on pneumonia no mention appears to have been made of Schoull and Weiller's method of treatment by the creosote enema. No one imagines that the use of creosote in respiratory affections is new for fifty years ago it was advocated in the treatment of pulmonary tuberculosis. But these authors, in their small brochure[1] of 70 pages, advise its use, not in chronic lung infections, but in the acute, particularly those due to the pneumococcus. Their method, briefly, is as follows. In pneumonia, after a wash-out enema, forty drops of pure creosote, *well shaken for several minutes* in 2 ounces of warm milk, are injected slowly well up the rectum. The enema should be retained about two hours. If not retained longer than half an hour it should be repeated, and in the adult ten drops of tincture of opium may be added to it. The dose in an adult should be repeated twice in twenty four hours. In children under 1 year two to ten drops in the dose, twice daily, in second infancy and adolescence five to ten drops, with an extra drop for each year. In old age less than forty drops may be given. The action of creosote in the purely pneumococcic condition seems to be almost specific, like serum, when it fails a streptococcic infection must be feared. It is interesting to note that in pneumococcic peritonitis Daru Loederich and Mamon[2] also advise its use for its selective action on the pneumococcus.

In the *Presse Medicale* (November 11th 1931) there is a useful summary of the value and details of the method. When our attention was called to this use of creosote we at once obtained some striking results in the treatment of *pneumonia at all ages*. We then applied it as a prophylactic in post-operative pulmonary complications. It quickly clears up catarrhal states in patients awaiting operation, and is now part of our routine preparation for all laparotomies or major operations of general surgery. In 150 cases of laparotomy of all types under open ether no case occurred of post operative pneumonia. But in two cases in which the enema was omitted by mistake pulmonary complications occurred—a broncho-pneumonia in a simple inguinal hernia, and a severe and prolonged congestion of the right lung in a gastrectomy for hour-glass stomach. Both patients recovered creosote being given at once on the appearance of the lung trouble. In urgent surgery we try to give the enema before the patient goes on the table if there is time, if not, immediately *after operation*.

Bassett[3] has also recently called attention to the value of creosote, in 174 operations, mostly gynaecological, no death occurred from lung complications when the drug was administered for some days before operation. Kocher,[4] over twenty years ago, evidently believed in its efficacy for he then wrote:

> We do not hesitate to give large doses of creosote when necessary two and a half drachms may be administered night and morning in the form of an enema. Dr. Rollier who has carefully investigated the action of this drug for some years has shown it prevents complications, and acts beneficially on the course of a pneumonia.

In these days when economy is necessary and three doses of Felton's serum cost approximately £10, it may be worth while giving another trial to creosote, administered in this simple way.—I am, etc.,

THE "SOBERING UP" RATE

SIR,—A matter of considerable medico-legal importance is raised by the question whether persons under the influence of alcohol "sober up" at the same rate or whether individual variation may be exhibited in this particular, such as is well known to occur in the process of becoming intoxicated. From inquiries made the latter view appears to be held widely and although I am unable to find any statement in current literature to the effect that the sobering up rate is constant for all persons, I venture to suggest that all the experimental evidence at our disposal supports that view.

Schweisheimer, Mellanby and others have shown that there is a close relationship between the concentration of alcohol in the blood at any given time and the symptoms

[2] *Journal de Chir.* October 1931.

[4] Kocher *Operative Surgery*.

accommodation required, and every effort will be made to make these charges as inclusive as possible.

Attached to the nursing home is a block of thirty-six consulting rooms occupied by members of the medical group to whose enterprise the nursing home owes its existence, and who will be responsible for its organization, although they have no concern in its finance. Their own relations are best described by the paragraph of their Articles of Association, that

"Every member of the Group shall have the right to carry on his private practice in his consulting room without any restriction and for his own benefit. In particular he may call in and have the advice and co-operation of any duly qualified medical practitioner, surgeon, or dentist, whether a member of the Group or not."

It is obvious that an undertaking of these dimensions, involving the capital outlay of nearly half a million sterling, cannot be carried out without an organized control. We have, however, endeavoured to combine the co-ordination which is essential to the success of any business undertaking with the liberty which has always been such a characteristic feature of British medical practice.—We are, etc.,

Universities and Colleges

UNIVERSITY OF OXFORD

The Francis Gotch Memorial Prize has been awarded to D. H. Hertz of New College.

UNIVERSITY OF BIRMINGHAM

Mr. Charles Rudd, M.B., F.R.F.P.S., ophthalmic surgeon to the Queen's Hospital, Birmingham, has been appointed a university clinical teacher in ophthalmic surgery at that hospital.

UNIVERSITY OF BRISTOL

The following candidates have been approved at the examination indicated:

FINAL M.B., CH.B.—*Part II:* F. W. A. Fosbery, J. A. Kersley, A. J. B. Miall, S. C. Wake. *In Group I (Completing Examination):* O. J. P. Bollon. *In Group I only:* A. C. Price. *Part I:* S. B. Adams, A. J. Board, Violet Fry, Winifred M. Hill (with distinction in Materia Medica, Pharmacy, Pharmacology, and Therapeutics), A. D. Jones, Gwladys R. Llewelyn (with distinction in Pathology), H. E. Pearse (with distinction in Pathology and in Forensic Medicine and Toxicology), Frances E. Powell, Mary G. Thomas.

UNIVERSITY OF DURHAM

On the nomination of the Senate, the Chancellor (Lord Londonderry) has appointed Sir Robert Bolam, M.D., LL.D., F.R.C.P., to be a Pro-Vice-Chancellor for the ensuing two years.

UNIVERSITY OF DUBLIN

SCHOOL OF PHYSIC, TRINITY COLLEGE

The following candidates have been approved at the examination indicated:

FINAL MEDICAL EXAMINATION.—*Part II, Medicine:* *A. A. Cunningham, J. A. Wallace, I. G. L. Ford, J. Miller, O. W. S. FitzGerald, Dorothy R. R. Solomons, E. Morrison, H. J. Eustace, E. S. Samuels, J. A. Page, A. J. Harden, E. W. West, H. St G. Smith. *Surgery:* *A. A. Cunningham, H. F. G. Irwin, G. A. Wray, J. A. Wallace, I. G. L. Ford, J. B. Fleming, R. C. Sutton, O. W. S. FitzGerald, E. FitzG. Burton, J. A. Page, E. W. West, A. P. Barber, H. J. Eustace, J. Miller, C. H. Hutchinson, D. Nolan, J. L. Martin, R. D. Scott. *Midwifery:* *J. J. Russell, J. L. du Pre, C. J. Hassett, P. H. Stone, S. Brass, C. H. M'Mahon, P. P. Murphy, C. J. Mullen, C. de V. Shortt, Edith M. P. Brodrick, M. Fallon, R. M'Neilly, P. G. Daly, Ray G. Barron, W. J. Craig, A. L. Pennefather, J. W. Craig, G. C. V. O'Driscoll, A. Pollitt.

* Passed on high marks.

NATIONAL UNIVERSITY OF IRELAND

At the meeting of the Senate on December 3rd a report from Dr. Denis J. Coffey, as representative of the University on the General Medical Council at the November session, 1931, was considered.

Dr. Edward J. Conway was appointed Professor of Biochemistry and Pharmacology in University College, Dublin.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH

The annual meeting of the Royal College of Physicians of Edinburgh was held on December 3rd. Dr. Robert Thin was elected President. The following were elected to form the Council for the ensuing year: Sir Norman Walker, Dr. Robert A. Fleming, Dr. William Fordyce, Dr. Edwin Bramwell, Dr. Edwin Matthew, and Dr. A. Fergus Hewat. Sir Norman Walker was nominated Vice-President.

At an extraordinary meeting held at the close of the annual meeting, Dr. G. Lovell Gulland and Dr. William Fordyce were elected representatives of the College on the board of management of the Edinburgh Royal Infirmary for the ensuing year. John Wheeler Dowden, President of the Royal College of Surgeons of Edinburgh, was elected an honorary Fellow of the College.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND

At the monthly business meeting of the College, held on December 4th, Surgeon Commander Richard L. G. Proctor, R.N., was admitted to the Membership.

The following were admitted Licentiates in *Medicine* and Midwifery under the conjoint scheme with the Royal College of Surgeons in Ireland: P. J. Byrne, E. S. Cooke, R. P. S. Lewer, J. A. McGuinness, P. J. MacMahon, T. F. Quigley, F. E. Reilly, F. H. Ryan, J. J. Walsh.

The representative of the College on the General Medical Council reported on the recent proceedings of the Council.

ROYAL COLLEGE OF PHYSICIANS AND SURGEONS OF CANADA

The second annual meeting of the Royal College of Physicians and Surgeons of Canada took place at Ottawa on November 19th, with the President, Dr. J. C. Meakins of Montreal, in the chair. The morning was occupied by a meeting of Council. Approximately 160 Fellows were present for the annual meeting of the College in the afternoon. The Fellows and their wives were entertained in the evening by their Excellencies the Governor-General and Countess Bessborough, at Rideau Hall.

The newly elected President of the College is Dr. F. N. G. Starr of Toronto. Dr. W. T. Connell of Kingston becomes Vice-President in the Section of Medicine, and Dr. P. C. Dagneau of Quebec Vice-President in the Section of Surgery. Dr. T. C. Routley of Toronto continues as Registrar-Secretary. The following were elected members of Council: Dr. J. C. Meakins (Montreal), Dr. Duncan Graham (Toronto), Dr. K. A. MacKenzie (Halifax), Dr. A. Rouseau (Quebec), Dr. J. E. Dube (Montreal), Dr. A. T. Bazin (Montreal), Dr. N. J. Maclean (Winnipeg), Dr. E. L. Pope (Edmonton), Dr. A. K. Monroe (Edmonton), Dr. L. J. Austin (Kingston), Dr. George C. Hale (London, Ont.), Dr. H. A. Farris (St. John, N.B.), Dr. A. H. Gordon (Montreal), Dr. Charles Hunter (Winnipeg), Dr. J. G. FitzGerald (Toronto), Dr. R. E. McKechnie (Vancouver), Dr. W. Harvey Smith (Winnipeg), Dr. W. E. Gallie (Toronto), Dr. A. Primrose (Toronto), Dr. E. W. Archibald (Montreal), Dr. W. W. Chipman (Montreal), Dr. H. G. Topping.

SOCIETY OF APOTHECARIES OF LONDON

The following candidates have been approved at the examination indicated:

MASTER OF MIDWIFERY.—J. T. Cameron, Mary D. Rankin.

Obituary

SIR T. EUSTACE HILL, O.B.E., M.A., M.B.

Lately Medical Officer of Health to the County of Durham, and Professor of Hygiene, University of Durham College of Medicine

The death of Sir T. Eustace Hill took place, under very sad circumstances, on November 25th, at Parkstone, Dorset, where he had been living since his retirement, eighteen months ago, from the position of county medical officer for Durham.

Thomas Eustace Hill was born in Birmingham in 1865. He was a son of the late Dr. Alfred Hill, medical officer for that city, who died only two or three years ago at a great age. The name of Hill of Birmingham stands boldly in the annals of public health. Dr. Alfred Hill's eldest son, Professor Alfred Bostock Hill, is emeritus professor of hygiene and public health at the university there. Perhaps it accounts for not a little of Eustace Hill's reforming zeal that his boyhood was spent in the stimulating atmosphere of the Birmingham of the 'seventies, when social reform was pursued with extraordinary eagerness under the inspiration of the radical mayor, Mr. Joseph Chamberlain, and the history of modern urban sanitation may be said to have begun.

After receiving his early education at the King Edward School in the Midland city, Hill went to Edinburgh University, where he graduated M.B., C.M. in 1887. In the following year, having taken also the B.Sc. in Public Health, he returned to his native Birmingham, and occupied for a short time the position of medical officer to the Isolation Hospital there and deputy medical officer of health. By 1890, however, he had found his life's work in the county of Durham. He served first of all for two years as medical officer of health for South Shields, and in 1893 he became medical officer to the county, a post which he held until 1930, when he retired under the age limit amid a wealth of tributes to his worth and work.

Durham, when Eustace Hill went there, was one of the most backward areas in England from a public health standpoint; he left it one of the most progressive. Typhoid and other former scourges were virtually stamped out during his reign at the Shire Hall. The infant mortality rate, which had been something like 300 per 1,000 births, fell to 73. Overcrowding and dreadful housing conditions were ameliorated. A network of health services extended from the Tyne to the Tees. The same influences which made for public health progress in the rest of England were, of course, affecting Durham, but in Durham they would certainly not have gone so far nor been so effective without the personality and driving force of the medical officer. He was an ardent reformer, but his unvarying charm, his courtesy, his virility, his devotion to high ideals, continually won over the reluctant, and spurred on the lethargic. He inspired everywhere respect and affection for himself, and therefore confidence in his administrative gifts, and a willingness to give his reforming projects fair play. He had an astonishing influence with his council, partly, perhaps, because he believed in the county as such—that is to say, in the value of county administration—and he was prepared to fight for it. In later years he appeared more than once as an expert witness on behalf of county councils at inquiries when county boroughs were seeking to extend their boundaries at the county's expense.

Whatever his own political views may have been, Hill's instinctive social sympathies in a densely populated industrial area like Durham gave him an understanding of Labour ideals, and he was proud to serve one of the two county councils—the other being Glamorgan—where Labour was in power. Speaking at the annual dinner of the Society of Medical Officers of Health a year ago, he said that he had found Labour control not a bad thing from the point of view of the medical officer of health, and he went on to relate instances of sympathetic understanding with his own work which had been shown him by working men and their leaders, especially by the chairman of his public health committee, a checkweighman at a colliery.

In 1911 Dr. Hill succeeded his friend, the late Dr. H. E. Armstrong of Newcastle, in the professorship of hygiene and public health at the University of Durham. He gave up the chair in 1920, owing to a multitude of other duties, but he retained the post of examiner in public health until his retirement from Durham. During the war he served in the R.A.M.C., and held the rank of lieutenant-colonel.

During the last ten or fifteen years he took a more prominent part in general professional affairs. He was always one of those medical officers who "got on" with the general body of the profession. He occupied during the same period—1921–22—the presidency of the North of England Branch of the British Medical Association and of the Northern Branch of the Society of Medical Officers of Health, his second tenure of the latter office. In the same year he succeeded to the presidency of the Society of Medical Officers of Health, and later was president of the Association of County Medical Officers.

Although he was a member of the Central Council of the British Medical Association only for one year, and of the Representative Body only for five, he served on many of the Association's committees, and his was one of the names immediately thought of when some work affecting public health required to be done. He served on the old Ministry of Health Committee, on the Public Health and Hospitals Committees at various times, on the Private Practice Committee, and on the subcommittee formed to deal with maternity and child welfare. He also took part in Government inquiries, and was a member of the Consultative Council of Medical and Allied Services to the Ministry of Health and of the Departmental Committee on the Training of Midwives. The efficiency of the midwifery service was one of his great interests. He had devoted much attention to perfecting this in Durham, and those who attended the Winnipeg meeting of the Association last year will recall his effective extempore

address in which, evidently impressed by the relative backwardness of midwifery organization in Canada, he described what had been done in England, and urged on Canadian medical officers and others a careful study of the question. He was president of the Section of Public Health at the Annual Meeting at Bath in 1925, and vice-president of the corresponding Sections at the Newcastle meeting in 1921, and the Winnipeg meeting in 1930.

The announcement of his retirement astonished many who knew him, for his youthful appearance made it difficult to believe that he had reached the age limit. An ardent pursuit of cricket, tennis, hockey, and boating in earlier years, and of golf later, kept him young and alert in the midst of many duties. There was every expectation of a long period of happy retirement and of wider service.

Dr. JAMES R. WHITWELL writes:

I should like to pay my tribute to the memory of my very dear friend Eustace Hill. We were close friends as students and friendly rivals for various university honours, and we kept in touch until death unlinked us. I have never met a finer character—high ideals, great thoughts, noble aspirations, and deadly in earnest in all he undertook—absolutely sincere and straight, and without much use for the word "expediency."

[The photograph reproduced is by Jas. Bacon and Sons, Newcastle-upon-Tyne.]

ARTHUR TAYLOR WEAR, M.D.

Newcastle-upon-Tyne

By the death of Dr. Arthur T. Wear in his eightieth year, Newcastle loses its oldest medical practitioner.

Born at Kingston-upon-Hull in 1852, he went to Newcastle-upon-Tyne at the age of 7, and was educated at the famous academy of the late Dr. Collingwood Bruce. Later, he underwent his professional training at the University of Durham College of Medicine and at University College, London. An interesting link in the progress of medical education emerges from the fact that, the days of medical apprenticeship having recently departed, he held, from November, 1872, to April, 1873, the office of resident clinical assistant (unqualified) at the Newcastle Infirmary. Since about 1887, these resident clinical assistantships, which afforded excellent opportunities to final-year students gaining clinical experience, have been replaced by other methods of instruction. In 1873-74 Wear qualified as M.R.C.S. and L.R.C.P., and in 1892 received the degree of M.D. in the University of Durham. From his student days he showed much interest in pulmonary tuberculosis, and eventually became one of the founders of the Northern Counties Chest Hospital. He held the post of honorary physician to that institution for fifty years, a record of service that found public recognition in the presentation made to him on his retirement two years ago. His other public appointments were those of honorary consulting surgeon to the Newcastle-upon-Tyne Dispensary, medical officer to the Salvation Army Rescue Home, and physician to the Hospital of St. Mary the Virgin.

In younger days he was keenly interested in the Volunteer movement, and served with the Newcastle R.G.A. for seventeen years, attaining the rank of surgeon lieutenant-colonel. For some time he was chairman of the Newcastle Division of the British Medical Association, and in that capacity did good organizing work, holding the respect and esteem of his fellow practitioners. He also represented the North of England Branch on the Council from 1905 to 1909, and the Newcastle-on-Tyne Division in the Representative Body from 1903 to 1906. He retired in 1929, and, after two years of failing health, he died on November 22nd, 1931. The funeral was very largely attended, both by the public and by his medical colleagues.

Dr. Wear was thrice married, and leaves a widow, four sons, and four daughters. Two of his sons follow him in a medical career, the elder in the public health service, and the younger succeeding to his father's practice.

The MEDICAL SECRETARY adds: I have particular reason to remember Dr. Wear with affection and gratitude. As a student beginning my medical career at the University of Durham College of Medicine I went to him as dispenser and assistant (this was in the days before unqualified assistants were abolished by the General Medical Council) I was with him till I qualified in 1891, and look back on the time I lived with him as perhaps the most fruitful part of my education. Dr. Wear was a very conscientious practitioner. He believed in hard work and inculcated it, to the best of his ability, into a succession of men like myself, who were thus initiated into general practice and the handling of patients in a way which later stood them in good stead. He had a stern sense of duty, and a high ethical standard in his relations with fellow practitioners. As an honourable man and a good doctor his memory will be honoured by all who knew him well.

We regret to record the death, on November 27th, of VINCENT DORMER HARRIS, M.D., F.R.C.P., consulting physician to the City of London Hospital for Diseases of the Heart and Lungs, and to the Royal National Hospital, Ventnor. Passing at the age of 80, after thirty years of retirement in his country home in Hampshire, the name of Vincent Harris will be remembered by his surviving contemporaries as that of a conscientious physician and a good friend, who did an immense amount of useful work without any thought of personal advancement or reward. Educated at St. Bartholomew's Hospital, he took a prominent place as a student, and held the post of demonstrator of physiology, subsequently becoming editor of some of the earlier editions of *Kirkes's Physiology*. He was elected a Fellow of the Royal College of Physicians as long ago as 1885, and was for many years an examiner. Leaving London about 1900, he settled down at Milford-on-Sea in Hampshire, and manifested his continued interest in hospital management by constant attendance at the board of the Ventnor Hospital and by helping to establish a cottage hospital in his own district. As a county magistrate, also, he took part in many local institutions, and the remarkable gathering of all classes on the occasion of the funeral at Milford bore touching evidence of the respect and affection in which his memory was held by those who knew him best.

Readers of the *British Medical Journal* who are aware of their debt to the printing office will appreciate the loss we have suffered by the death of Mr. J. F. BRUNETTE, on December 5th, less than three and a half years after the death of Mr. Lapworth, his predecessor in the post of head printer. Mr. Brunette was highly skilled in his craft, and faithfully served the Association for thirty-three years. A most conscientious and resourceful worker, his long experience in the business of medical typography was always at the service of the editorial department, and he responded loyally to every fresh call on his time and energies.

The following well-known foreign medical men have recently died: Dr. AUGUST SCHARNKE, extraordinary professor of psychiatry and neurology at Rostock University, aged 46; Dr. ARTHUR SCHNITZLER of Vienna, the eminent playwright and novelist, aged 69; Dr. ARTHUR SIMARD, professor of surgery at Laval University; Professor GUSTAV FINDER, aged 64, Berlin oto-laryngologist and editor of *Zentralblatt für Hals- Nasen- und Ohrenheilkunde*; several years; and Dr. JUSTIS BARTH, a prominent gynæcologist and obstetrician of Oslo, aged 68, of angina pectoris.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

The House of Commons was occupied this week with the Bill to authorize the taxation of out-of-season horticultural produce imported from abroad. A general discussion of policy followed on a vote of censure moved by the Opposition, and the motion for the Christmas adjournment was to be taken on December 11th. The House is due to reassemble on February 2nd.

In the House of Lords, on December 8th, the National Health Insurance (Prolongation of Insurance) Bill was read a third time and passed.

In the House of Commons, on December 8th, the Horticultural Products (Emergency Customs and Duties) Bill passed through committee. Dr. Salter supported an amendment to exempt tomatoes from the customs duty. He said that the tomato, which contained all the vitamins necessary for dietetic purposes, was an essential item of diet among three-quarters of a million poor people in South-East London, who could not afford to purchase other vegetables in sufficient quantities. The amendment was negatived.

B.C.G.

On December 7th Sir F SANDERSON asked the Minister of Agriculture to take steps to ensure that the Calmette or B C G vaccine was not used on farm animals in this country without his consent. Sir JOHN GILMOUR replied that he was informed that vaccine cultures had been distributed by Professor Calmette to responsible medical and veterinary authorities for experiment and trial In this country three veterinary laboratories were supplying vaccine to veterinary surgeons for the treatment of calves born in certain selected infected herds, but no case had been brought to his notice in which the vaccine was alleged to have produced harmful effects He understood that the vaccine was not being sold by commercial firms, and was not obtainable by the public He did not propose to restrict the work of the laboratories engaged on farm trials of the vaccine.

Small-pox

On December 1st Sir E HILTON YOUNG, replying to Mr. Groves said that sixteen deaths occurred among the small-pox cases tabulated on page 49 of the Report of the Chief Medical Officer of the Ministry of Health for 1930. Those deaths, following the classification adopted in the tabular statement, were distributed as follows successfully vaccinated, 5 deaths, of persons aged 46, 47, 56, 66, and 77 years respectively, successfully revaccinated, no deaths, unvaccinated, 8 deaths of persons aged 3 weeks, 4 weeks, 7 weeks, 8 months, 8 months, 10 years, 11 years, and 13 years respectively, vaccinal condition doubtful, 3 deaths, of persons aged 45 58, and 59 years respectively. As the table related to certain districts only, and the total number of deaths from small-pox during the year was given elsewhere in the report, it was not necessary to arrange for the deaths, if any, to be included in the table

Insurance Medical Service

Sir E HILTON YOUNG told Dr. Hillman, on December 3rd, that a proposed Regulation under the National Health Insurance Acts to regularize the practice of permitting a doctor to charge a fee for treating an insured person, if such person declared in writing that he did not desire treatment under the Insurance Acts, had not yet been actually made or published in draft. The requirement of a written declaration was designed to safeguard the interests of insured persons. The provision was proposed by the Ministry of Health itself for inclusion in a general redraft of certain parts of the Medical Benefit Regulations designed to make them clearer and easier to administer in regard to fee charging and other matters. He had no information suggesting that doctors would make large sums of money out of the new Regulation and recoup themselves for their losses on the "economy" proposals In reply to Dr. O'DONOVAN, he said he had no statistics showing to what extent advantage was still taken of the special conditions, which provided that a panel practitioner might accept fees in respect of treatment given to an insured patient not on the practitioner's list.

Sir E. HILTON YOUNG informed Mr Rhys Davies, on December 7th, that the actuary's report on the third valuation of approved societies had been laid before Parliament and was being printed. Publication within a week or two therefore might be expected.

Foot and mouth Disease

Sir JOHN GILMOUR, replying on December 7th to Mr Hurd, who asked what administrative action he proposed to take following on the conclusion of the Government of Northern Ireland that the outbreak of foot-and-mouth disease in this country last summer had its origin in vegetables imported direct from disease-ridden countries on the Continent, said that the only effective action possible would appear to be in the direction of the prohibition of imports How far such action was justified and practicable must be determined in the light of all the circumstances The information at the disposal of his Department would not at present justify such action in the case of Continental vegetables The position, however, would continue to be carefully watched Mr HURD asked if the vegetables which carried the virus of this disease were still being imported Sir JOHN GILMOUR said that in numerous cases foot-and-mouth disease had been attributed to this source, but that had not been the case in general

Ministry of Pensions.—Major TRYON replying to Mr Jo l on November 30th, stated that the cost of administration of the Ministry of Pensions for each of the five years ending on March 31st next was 1927–28, £1 505 000, 1928–29, £1 290,000, 1929–30 £1,295,000, 1930–31 £1 221 000 and 1931–32, £1 039,500 (estimated) At the end of September last 430 000 final awards of disability pension or retired pay were in payment For the year ended September, 1930, fresh applications from all classes of claimant including disabled officers and men, widows, and dependants numbered 24,600, and for the year ended September last 13,600 Awards of pensions or other grants were made in 3,570 cases in the former year, and in 3,170 in the latter Answering a supplementary question by Captain Crookshank, Major TRYON said that the total expenditure on war pensions since 1914 was £1,015,000,000.

Dangerous Drugs.—Sir HERBERT SAMUEL told Dr Fremantle, on December 2nd, that before the British Government could ratify the 1931 Convention for the limitation of the manufacture of narcotic drugs the Dangerous Drugs Act would require amendment in certain minor respects A Bill was now in preparation.

Russian Butter.—On December 8th Mr E BROWN, replying to Sir W. Davison, said that the Minister of Health was aware of statements in the press in regard to recent Russian official statements as to the insanitary condition of many of the farms where milk was produced in Russia Russian butter, with other foods, was subject to examination on arrival under the Imported Food Regulations and the Preservatives Regulations. The Department had not investigated the conditions under which the butter was produced but arrangements were made last summer for samples of the butter to be examined bacteriologically The reports on these examinations were satisfactory but the Minister was considering the desirability of further similar examinations

Miners' Vaccinations.—Mr ISAAC FOOT said that it would be impossible with reasonable accuracy to state the number of miners who had been refused employment underground owing to having drawn compensation for nystagmus.

Medical News

Mr. E. Muirhead Little, consulting surgeon to the Royal National Orthopaedic Hospital, is to read a paper to the Historical Section of the Royal Society of Medicine on January 6th, at 5 p.m., on "The introduction of tubercle into bone and joint surgery." This will be of special interest in view of the fact that 1932 marks the fiftieth anniversary of the discovery of the tubercle bacillus.

At a meeting of the Royal Microscopical Society, to be held at the B.M.A. House, Tavistock Square, W.C., on Wednesday, December 16th, at 5.30 p.m., Dr. Edward Hindle will read a paper on thermophilic micro-organisms. The annual general meeting of the Society will be held on January 20th, 1932, when Professor R. Ruggles Gates, F.R.S., will deliver his presidential address.

The Royal Society of Medicine will hold a reception at 1, Wimpole Street, W.1, on Monday, December 14th, at 8.30 p.m. Fellows and their friends will be received in the library by the President and Mrs. Watts Eden, and at 9.15 p.m. a cinematograph film will be shown. Admission will be by ticket only, applications for which should be addressed to the secretary.

The annual medical dinner of the Birmingham Medical School will be held in the Grosvenor Rooms, Grand Hotel, Birmingham, on January 28th, 1932, at 8.15 p.m. The guest of honour will be Professor Leonard Gamgee, to whom a presentation is to be made by his past students upon his retirement from the chair of surgery, which he has occupied since 1919. Donations are limited to £1 1s., and it is hoped that as many past students as possible will subscribe towards the presentation, and also be present at the dinner. The cost of the dinner ticket is 10s., but for students and residents the charge is 7s. 6d. Tickets can be obtained from Mr. Cyril A. Raison, F.R.C.S., 85, Cornwall Street, Birmingham.

The Fellowship of Medicine and Post-Graduate Medical Association announces the following free demonstrations: Royal Waterloo Hospital, Tuesday, December 15th, 2 p.m., Dr. Bernard Myers on pulmonary affections of childhood; Miller General Hospital, Thursday, December 17th, 11 a.m., Mr. Reginald Ledlie on varicose vein injections. The next series of Wednesday afternoon lectures (free to the profession), at the Medical Society of London, 4 o'clock, will be on treatment, beginning on January 13th. A course of six lectures on endocrinology (detailed syllabus now ready) will be given at the Medical Society by Dr. Langdon Brown at 8.30 p.m., Mondays and Fridays, January 11th to 29th, 1932; fee, £3 3s. for course, or 12s. 6d. per lecture. A special evening M.R.C.P. course is being arranged by the Fellowship for February 22nd to March 18th. Six clinical and two pathological evenings will be given at the London Temperance Hospital, ophthalmic demonstration at the West End Hospital for Nervous Diseases, lecture and laboratory demonstration at 10, Bedford Square, and four lectures at the Medical Society (number of post-graduates at demonstrations limited to 25).

A new series of lectures and practical courses for the Diploma in Psychological Medicine will open at the Maudsley Hospital on January 4th, 1932. Dr. F. Golla will give twelve lectures on the physiology of the nervous system, and four lecture-demonstrations on physiological psychology. Four lectures on biochemistry in relation to the nervous system will be given by Mr. S. A. Mann, D.Sc.; twelve lectures on the anatomy of the nervous system by Mr. W. Le Gros Clark; practical instruction and demonstrations by Mr. Charles Geary; eight lectures on psychology by Dr. Henry Devine, followed by a course of practical instruction; and six lectures by Dr. E. Mapother on mental mechanisms. Part I of the course will extend through January and February, and Part II from March to May. The fee for the whole course is £15 15s., for either part separately £10 10s., for single series of lectures in Part I £4 4s., for single series of lectures in Part II £2 2s., and for one series of demonstrations £1 1s. Inquiries should be addressed to the director of the Central Pathological Laboratory, Maudsley Hospital, Denmark Hill, S.E.5.

The executive committee of the second International Congress of Tropical Medicine announces that the congress which was to be held in Amsterdam from September 12th to 17th, 1932, has been postponed. Owing to economic conditions the Dutch Government feels unable at present to grant its financial support, and private contributions so far received have been inadequate to cover the estimated expenses of the meeting. The committee intimates that subscription fees which have already been paid will be returned without delay.

As announced in the advertisement pages of this issue, applications for the George Henry Lewes studentship in physiology, of the annual value of about £250, should be sent, by December 31st, to Professor Barcroft, Physiology School, Cambridge, from whom the regulations may be obtained.

The Alvarenga prize of the College of Physicians of Philadelphia for 1931 has been awarded to Dr. Edgar S. J. King, Melbourne, Australia, for an essay on "The nature of the stroma of the ovary." The next award of the prize, amounting to about 300 dollars, will be made on July 14th, 1932, provided an essay deemed worthy of the prize has been offered. The essay should be based on original or literary research in medicine, and should not have been presented elsewhere, in part or in whole, for a prize or for publication. It should be typewritten and unsigned, but marked with a motto, and accompanied by a sealed envelope having on its outside the motto, and within the name and address of the author. The successful essay will remain in the possession of the College, but, with its consent, may be published by the author. Rejected essays will be returned upon application within three months of the award. Essays should be sent to the secretary of the College, 19, South 22nd Street, Philadelphia.

The Ministry of Health is issuing this week as No. 66 of its Reports on Public Health and Medical Subjects an account by Dr. Janet E. Forber (*née* Lane-Claypon) of an investigation of hospital patients in Eastern London suffering from incurable cancer. It is published by H.M. Stationery Office at 1s. net.

On the occasion of his retirement from the office of medical officer of health for Ayr, Dr. W. F. Brown has been presented by the members of Ayr Town Council with two easy chairs as a memento of their esteem. Dr. Brown was secretary of the Ayrshire Division of the British Medical Association from 1914 to 1919, and chairman in 1929–30.

The issue of *Le Progrès Médical* for November 17th is devoted to therapeutics, and contains an illustrated supplement written by Professor C. Lenormant on French surgery in the eighteenth century, on the occasion of the second centenary of the Académie Royale de Chirurgie.

The Cambridge University Press announces for publication in January *The Cambridge Medical School: a Biographical History*, by Sir Humphry Rolleston, Regius Professor of Physic in the University.

The October and November issue of *Schmerz Narkose Anaesthesie* contains a concise history of chloroform since its discovery in 1831 by Samuel Guthrie.

The British Serbian Units Branch of the British Legion held its tenth annual dinner in London on the evening of December 5th. The president, Miss C. M. Mure, was prevented by illness from being present, and the chair was ably taken by Lady Berry, M.D., on her behalf. The Chargé d'Affaires, Dr. Pouritch, represented the Yugoslav Minister (who is out of England), and replied to the toast of "The Guests," proposed by Lady Berry. Major-General Sir Frederick Maurice, treasurer of the British Legion, proposed the toast of "The Branch and its President." During the evening Mr. P. H. Mitchiner F.R.C.S., presented a silver bell and silver spoons as prizes for miniature-rifle shooting, and after dinner the guests enjoyed Serbian and English dancing.

In order to inaugurate a new thermal establishment at Vichy, which is nearing completion, the Société des Sciences Médicales is holding an international congress on biliary lithiasis at the end of September, 1932. This congress will be the first of a series of medical meetings which will be held periodically at this town to discuss liver diseases and associated complaints.

A stained-glass window, in memory of Dr. S. H. A. Lambert of Harrow, is to be placed in Roxeth Parish Church, but many of his friends feel that there should be a memorial also at the Harrow and Wealdstone Hospital, with which he was most intimately associated, and a fund for this purpose has been opened. It is suggested that the men's ward in the extension to the hospital should be endowed in Dr. Lambert's memory and bear his name.

The Golden Square Throat, Nose, and Ear Hospital, near Piccadilly Circus, has recently opened two contributory wards, one for men and one for women. These wards have been redecorated and refurnished, and divided into cubicles. The charge for admission is four guineas a week, inclusive.

In the report for the year 1930, the Blind Relief Association, Bombay (the first of its kind in India), describes measures taken for the prevention and treatment of blindness. Centres exist at Surat, Bulsar, Anaud, Chalisgaon, and Bijapur. Relief is provided for people of all ages and of both sexes, irrespective of creed, caste, or colour.

We have received the first issue, dated last October, of *Archivio Italiano delle Malattie dell' Apparato Digerente*, which will be published bi-monthly by L. Capelli of Bologna, under the editorship of Professors C. Frugoni and G. N. Fasiani of Padua and A. Busi of Rome, and is intended for physicians, surgeons, and radiologists specially interested in diseases of the digestive system. The subscription is 80 lire for Italy and 100 lire for foreign countries.

The annual report of the Lester Chinese Hospital, Shanghai, for 1930 reveals that 46.7 per cent. of the in-patients and 37 per cent. of the out-patients come from the International Settlement. The number of patients in the emergency department reached a total of 9,400, mainly owing to a large increase in traffic accidents and wounds from assaults. This side of the work is a costly matter, in view of the fact that very little financial recompense can be made by the victims.

Dr. Bernard Day has been appointed by the Secretary of State for the Colonies to be one of the consulting physicians in London to the Colonial Office.

Dr. Arthur Stanley Woodwark has been appointed a Deputy Lieutenant for the County of London.

Sir Norman Bennett has become president of the British Dental Hospital, in succession to the late Sir Harry Baldwin.

The late Mrs. J. Thompson Long of Bath, who left estate of £45,324, with net personalty £39,601, bequeathed all her property (subject to legacies amounting to £5000) in trust for her husband for life, and then one-half to St. Thomas's Hospital to endow beds for the free and separate treatment of aged and necessitous gentlefolk, and the other half in like manner to the Hospital for Sick Children, Great Ormond Street, for the benefit of children of necessitous gentlefolk.

A marble bust of the late Dr. Giovanni di Cristina, professor of children's diseases at Palermo, who died in 1928, has recently been unveiled in the grounds of the Palermo Children's Hospital.

Professor Cesare Frugoni of Padua, the author of works on asthma, pulmonary oedema, and splenomegaly, has been elected successor of the late Professor Ascoli in the chair of clinical medicine at Rome.

A new pathological institute has recently been opened at the Sen Yatsen University in China, under the direction of Dr. Ernst Dormanns.

Dr. Charles Nicolle, director of the Institut Pasteur of Tunis, has been nominated Commander of the Legion of Honour.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed *to The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.*

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors *desiring REPRINTS of their articles published in the British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and *the British Medical Journal* are *MUSEUM* 9961, 9962, 9963, and 9964 (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Articulate Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Medisecta Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS

Cellulose Spraying

"T. M. G." writes: Are there any toxic symptoms to be expected in a man who does a great deal of cellulose spraying in the process of finishing motor-car bodies? Some of the patient's friends tell him that he will get very bad indigestion and septic sores. The only thing I have noticed (during the three or four years he has been on the spraying job) is that he seems very liable to sores which take a long time to heal.

Nausea and Vomiting of Pregnancy

Dr. A. ELLIOTT (*Sparkbrook, Birmingham*) writes: In answer to the query of Dr. Lawson L. Steele (November 28th, *p. 1017*) as to effective treatment for the vomiting of pregnancy, I should like to ask whether he has tried sodium luminal, or its *B.P.C.* equivalent, sodium phenobarbitol. I have found that one-half to one grain of this drug administered at night will often completely control the condition which, however, tends to start again if the drug is omitted. In these doses it seems to have no toxic effect, even if used for long periods.

Dr. A. L. MARTYN (*Crantock, Cornwall*) writes: Allow me to suggest the old device of drop doses of recently made tinct. nucis vom. in a drachm of fresh water, taken on waking *in the morning*, and, say, *twice again before breakfast*; and if it be possible, also a teaspoonful of good Italian salad oil in coffee or wine, also some time before breakfast. Provided other things are equal, I have never known this remedy to fail.

"M." writes: I suggest that Dr. Steele should try liq. adrenalini hydrochlor. (1 in 1,000) in 2 or 3 minim doses by mouth after food; this should be accompanied by an extra intake of sugar in some form. I have noticed in several of these cases that there is a definite distaste for sweet things, and patients have found sugar to be the least disagreeable in the form of actual lumps which they crunch and swallow as quickly as possible. I have not been able to investigate these patients (other than observe the fact that the vomiting and nausea are definitely lessened), but the best explanation I can suggest is that there may be some hypoglycaemia in these cases and that the adrenaline raises the blood sugar and presumably counteracts the tendency to an alkalosis.

Cobalt

Income Tax

Replacement of Car

"D. R." bought a car in 1928 for £35; in 1931 he sold it and bought another for £185. What should he claim, on the basis that five-sixths of the use of the car is professional?

*** As an expense of the practice—five-sixths of (£35 − £*x*), £*x* being the amount which the old car realized. The excess of £185 over the net cost of the old car represents capital outlay. The deduction will reduce the amount of the net profits for 1931, and therefore the income tax assessment for 1932–33; consequently "depreciation" cannot be claimed for that year, but should be claimed for 1933–34, unless another replacement is effected in 1932.

Cost of Maintenance of Assistant

"G. J. H." employs an indoor assistant. In calculating his profits he has deducted an agreed amount covering one-half the cost of two maids and one-half of the Schedule A assessment, rates, lighting, and heating, etc., of the house as representing the expense of providing and maintaining the professional portion of the establishment. What would be a fair deduction for the cost of maintenance of the assistant?

*** A great deal must depend on the precise facts—for example, what standard of living is maintained, and what proportion of the house is used by the assistant personally. The cost of maintenance elsewhere is not necessarily a reliable guide, as that would include an element of profit and of payment for the services of the "landlady," whereas all "G. J. H." is entitled to charge is the cost of the assistant's food, laundry, etc., plus a proportion of that moiety of the general expense of maintenance of the establishment not already allowed for in the calculation. Prima facie, £3 per week is too much on that basis, but the inspector's figure of 25s. per week seems inadequate; 35s. would seem nearer the mark than either of these figures.

Withdrawal of Car Allowance

"D.P.H.Camb." bought a new car for £240 on the strength of a decision by the appointing local authority to give him an allowance of £65 per annum for use of a car in his work. It is now proposed to withdraw the allowance on grounds of economy. The car is worth £120. Can any claim be made for this "loss"?

*** No. The only claim that seems valid is that as from the withdrawal of the "allowance" a deduction at a corresponding rate should be made from the amount of the salary as representing the necessary expense of maintaining the car; alternatively, a claim for the actual expenditure incurred in running the car after that date can be made. It has to be remembered that as the income is assessable on the basis of the earnings of the previous year, the above adjustments will affect liability for 1932–33, not 1931–32.

LETTERS, NOTES, ETC.

The "Medical Directory"

No reference book is consulted so often in this office as the *Medical Directory*, and it would be ungrateful to let a new edition appear without testifying again to its value. So far as can be judged from a preliminary survey, the eighty-eighth annual issue, for 1932 (J. and A. Churchill, 36s.), fully maintains the standard of its predecessors in the matter of accuracy and compendiousness. The numerical summary, which will be found near the contents page, shows that this volume includes 55,480 names, representing an increase of 445 on the total for 1931. The figures for London, the Provinces, and "Abroad" have increased; Ireland is almost unchanged; and there are slight decreases in Scotland, Wales, and the Services. Dr. Fortescue Fox's medical notes on British spas and seaside resorts have been revised and amplified. The "Late List" of new names and changes of address appears at page 2122, following the list of certified institutions and houses under the Mental Deficiency Act.

Age Limits

"ECONOMY" writes: I agree with "Juvenis" (November 28th, p. 1018) on the absurdity of limiting medical appointments to the age of 45. We hear a great deal nowadays on the subject of national economy, yet the State overlooks the fact that the public health service is a closed door to medical officers of the fighting services, who have been retired from the Army or Navy at the age of 55. A large proportion of such officers have specialized in public health work, taken the D.P.H., and spent twenty to thirty years actively employed in keeping a high standard of health in the fighting forces of the country. These officers are kept up to date by the necessity of passing examinations for promotion, and do a long post-graduate course before promotion to higher ranks. Here, then, exists a pool that could supply many candidates to the public health services—efficient men of experience; yet the State that has helped to make them efficient by paying for their special training in public health work has no use for them after the age of 55, and allows them to idle out the rest of their lives on small pensions. Very few men wish to be idle at 55, even if they can afford to be, and I am confident that a guarantee of further employment under the Crown for medical officers who specialized in public health during their service would do much to popularize the medical branches of the Army, Navy, and Air Force.

Early Use of Liver in Medicine

Dr. E. J. TYRRELL (London, E.C.) writes: In your notice of the *Medical Art Calendar*, 1932, it is said: "The first use of liver in medicine would seem to be of ancient origin, for the Angel Gabriel turned heart and liver of a haddock to beat the devil so that Tobit might marry his bride." It was not the Archangel Gabriel who did this, but the Archangel Raphael. The story runs thus: "As he went, he remembered the words of Raphael, and took the ashes of the perfumes, and put the heart and the liver of the fish thereupon, and made a smoke therewith. The which smell, when the evil spirit had smelled, he fled into the utmost parts of Egypt, and the angel bound him." (Apocrypha, Tobit, 8, 2–3).

Prescribing British Drugs

"COUNTRYMAN" writes from Ayrshire: It appears to be certain that a major cause of this country's present financial position is the hoarding of gold by America and France. As a profession we have been called upon to accept cuts in our fees, and to many of us the income tax has become a still more dreadful worry. At present the campaign of "Buy British" should find as whole-hearted support among the profession as it is apparently doing among the general public. There must be an enormous amount of drugs of foreign origin prescribed with little more reason than that the drugs are "well pushed" by their energetic proprietors. In America, salesmanship has become a fine art, and every practitioner who prescribes an American preparation when there is an equally satisfactory British one is paying tribute to American cleverness. He is also sending more gold unnecessarily to America, and more gold to France when he prescribes a French remedy for which there is an equally satisfactory British substitute. The number of active and proved foreign preparations for which there is no British equivalent must be very small. Of course, the interests of the patient come first, but I would plead with the prescriber to pause with pen in hand and not sign away British gold carelessly and needlessly to those countries whose financial policies have added to his already heavy load of cares.

Diaries and Calendars

We have received from Messrs. John Walker and Co. (Farringdon House, Warwick Lane, E.C.4) an attractive selection of diaries, calendars, memorandum pads, and appointment books. The habitual diarist will be pleased to find the customary information as to the moon's phases, lighting-up time, and the inland postal rates, whilst the pages devoted to cash accounts, which in most cases cease to be made use of during the early weeks of February, will satisfy the enthusiast. Those who, like ourselves, seldom do this, astronomically, will be interested to learn that there are four eclipses during 1932.

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals will be found at pages 40, 43, 46, 47, and 48 of the advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 44 to 45.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 318.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

532 The Significance of Large Q-Waves in the Electrocardiogram

F. A. WILLIUS (*Amer. Heart Journ.*, August, 1931, p. 723) has correlated the clinical findings in patients showing enlargement of the Q-wave in Lead III of the electrocardiogram. In his selection of tracings he has observed the following criteria of Pardee: (1) that only normal or left axis deviation was present; (2) the downward excursion of the Q-wave in Lead III was the initial deflection and more than 25 per cent. of the greatest QRS excursion; and (3) tracings with notching deformity of the QRS in Lead III were excluded. Among the 309 patients studied, only 0.1 per cent. had apparently normal hearts. In 89 per cent., hypertensive and arteriosclerotic heart disease was present, and this group included patients with or without the anginal syndrome. The remaining group of 11 per cent. was composed of a variety of conditions, such as exophthalmic goitre, syphilitic aortitis with insufficiency, and rheumatic heart disease. These were in general diseases that might throw a strain on the left ventricle. Pathological control was available in only nine of the cases; in eight there was considerable hypertrophy. The fact that four hearts showed no coronary changes supported the view that hypertensive disease was the dominant factor in the production of an enlarged Q-wave in Lead III. In two-thirds of the patients no other electrocardiographic abnormality was present, permitting the conclusion that this abnormality might be considered an additional diagnostic sign. The author has employed as a control for his series a composite group of electrocardiograms made from 977 normal individuals; in only 0.2 per cent. of this group were large Q-waves found in Lead III.

533 Contagiousness of Herpes Zoster

M. ESCARAVAGE (*Thèse de Paris*, 1931, No. 426), who records an illustrative case, and reviews the literature, states that the epidemic occurrence of herpes zoster has long been known, having been described by Celsus, Pliny, and Scribonius Largus. The true epidemics must be distinguished from the false, which are due to the coincidence of the same adjuvant causes, as in the case of epidemics of zoster in patients treated by arsenic or tuberculin. There do not appear to be any special etiological factors in zoster epidemics, the age, sex, season, and occupation being indifferent. The contagiousness of zoster is much less evident than its epidemic character, as hitherto only nine cases have been recorded, although Trousseau was the first to describe an example. Recent study of the relations between zoster and varicella has shown that the duration of the incubation period is about a fortnight; in at least two of the cases collected by the present author the incubation period was the same.

534 Circulatory Failure in Diabetic Coma

A. PEIPERS (*Deut. med. Woch.*, August 28th, 1931, p. 1499) agrees with the generally accepted view that the threat to the general circulation in diabetic coma arises from the acidosis, polyuria, and disturbance of the carbohydrate metabolism. Circulatory failure, a common premonitory symptom of impending coma, may occur suddenly after effort, but coma may appear without warning when conditions seem favourable. It may result in syncope leading to typical diabetic coma which, though delayed, is inevitably fatal. Peipers describes the case of a man, aged 57, who had had symptoms of diabetes for twelve months, and was on dietetic treatment. The odour of acetone in the breath was observed for about three weeks before coma supervened; he was very emaciated, and there was ocular hypotonus; the pupils were contracted, but reacted to light. The typical deep inspiration was present, and the pulse was small, soft, and rapid. The blood sugar figure was 450 mg. The patient was given insulin (50 units) and, simultaneously, glucose by the mouth. Hypoglycaemia supervened, accompanied by profuse sweating, tonic spasm, and jactitation; coarse bubbling pulmonary rales indicated serious circulatory failure. Glucose was administered by the nasal tube, the syncopal symptoms subsided rapidly, and the circulation improved. Seven hours later the blood sugar had risen to 600 mg., and two hours afterwards the man regained consciousness. Later he complained of severe thirst. Exertion produced dyspnoea, but the respiration improved, the rales disappeared, he was able to speak, and the acetone odour had disappeared. A glycerin injection produced a copious stool, but he then collapsed suddenly, with stertorous respiration. Cardiac stimulants and adrenaline produced transient improvement, but he died two hours later. Peipers considers that the sudden collapse after obvious clinical improvement was due to respiratory failure, induced by cerebral anaemia secondary to sudden lowering of the intra-abdominal pressure after defaecation, and consequent flushing of the splanchnic circulation.

535 Complications of Diabetes

F. D. MURPHY and G. F. MOXON (*Amer. Journ. Med. Sci.*, September, 1931, p. 301) believe that a diagnosis of diabetes alone is often incomplete; when the progress of a diabetic patient is unsatisfactory after he has been rendered sugar-free, the possibility of a complication being present must be seriously considered. An analysis of 827 cases of diabetes showed that 681 (82.37 per cent.) were complicated by one or more diseases, and, of these, 428 patients (69.2 per cent.) died. The 75 various complications are discussed under the following seven headings: diabetic coma, cardio-renal vascular diseases, infections other than gangrene, pulmonary tuberculosis, carcinoma, syphilis, and miscellaneous complications, such as epilepsy and hyperthyroidism. A complication usually interferes with the welfare of a diabetic patient, and indicates the probability of a fatal termination of the case. Hence, the early recognition and treatment, as well as prevention, of complications is highly important. E. L. SEVRINGHAUS (ibid., p. 311) also presents a study of 500 diabetics, 90 of whom died. The causes of death, in the order of importance, include sepsis, cardio-vascular renal disease, and coma; gas gangrene occurred only three times, and tuberculosis was infrequent. Pyogenic infection after gangrene, and pneumonia, were the commonest septic processes leading to death. Pains in the extremities were found in 36 per cent., and diminished or absent patellar reflexes in 46 per cent. Transitory visual disturbances were noted in 38 per cent. Ketosis at the time of the first examination indicates the need of insulin, its absence implying that this form of treatment is unnecessary.

536 Phosphaturia

L. H. BARETZ (*New York State Journ. of Med.*, September 1st, 1931, p. 1084) discusses persistent non-infected phosphaturia producing a cloudy alkaline urine, and associated with neurasthenia and intestinal derangement. The condition is caused by an absolute increase in the earthy phosphates, owing to an inability of the large bowel to excrete the normal amount; there may also be a low-grade infection of the prostate or seminal vesicles requiring routine massage for the removal of the foci. In the non-infected variety, dietary treatment is fundamental; the urine must be kept acid, and the alkaline tide be reduced by the omission or reduction of base-forming foods, such as vegetables and fruits, and increasing the meats and cereals. Any concomitant intestinal disorder must be dealt with, such as constipation and colitis, so that normal calcium excretion through the

intestinal tract may be produced, with a tendency to normal phosphatic urinary excretion. Medicinally, acid sodium phosphate or some other urinary acidifier should be given. Since there is frequently an associated neurosis, it is important that any psychic factor should be removed. Cystoscopic treatment is usually unnecessary, unless indicated by persistent renal colic or vesical symptomatology. Reports of three cases are given to illustrate the syndrome of phosphaturia with associated renal colic, excessive vegetable diet, intestinal disorder, and prostatic or seminal vesicular infection.

537 Catarrhal Gingivitis

R. E. PERL (*Wien. klin. Woch.*, September 4th, 1931, p. 1136) describes a constant type of gingivitis which formed part of a syndrome observed in seven cases in November–March, 1930–31. The preliminary symptoms were a day's malaise preceding a coryza, generally more marked on one side than the other, and a labial herpes. There followed an acute and painful gingivitis, generally also unilateral, a mild trachitis, occasionally bronchitis, and a recurrence of the labial herpes. The condition was generally associated with mild pyrexia, and subsided in a few days. In all but one of the cases the nasal secretion, the purulent deposit on the gums, and the sputum were examined bacteriologically, and in each case a short non-motile Gram-negative bacillus was found, belonging to the Pasteurella group of organisms ; this is regarded as the cause of the syndrome described. The organism was not present in a control series of cases of coryza in which the characteristic gingivitis did not occur.

538 Tularaemic Meningitis

J. O. HAZLIP and A. E. O. NEIL (*Journ. Amer. Med. Assoc.*, September 5th, 1931, p. 704), who record an illustrative case, state that apart from five fatal cases of tularaemia mentioned by Francis, which terminated with meningeal symptoms, no previous example of meningitis due to *B. tularense* has been recorded. Their patient was a man, aged 45, who developed meningitis secondary to a sore on the left thumb. *B. tularense* was found in the exudate from the thumb, and in the turbid cerebro-spinal fluid. The blood serum agglutinated a *B. tularense* antigen in a dilution of 1 in 40. Inoculation of guinea-pigs with the exudation from the thumb and the cerebro-spinal fluid produced typical tularaemia with the characteristic lesions.

Surgery

539 Etiology and Prognosis of Septic Empyema

E. SCHILDT (*Upsala Läkareför. Förhand.*, September 21st, 1931, p. 1) records his observations on 289 cases of septic empyema treated at the Upsala Surgical Clinic during the period 1916–29. All cases complicated by tuberculosis, actinomycosis, or tumour were excluded ; 282 were recent cases, 4 were recurrences, and only 3 were chronic cases. A considerable increase in the incidence of empyema occurred in the years when influenza was prevalent. Nearly 50 per cent. of the cases were found in the first 20 years of life, and over 70 per cent. in the first 30 years. The number of female cases showed a continuous rise with advance in age, while the number of male cases increased sharply about the 20th year as the result of influenza. More than 85 per cent. were undoubtedly, or probably, due to primary disease of the lung, and in more than 9 per cent. the etiology was obscure ; the remainder were secondary to trauma, pyaemia, infections of the thorax, or abdominal disease. In only a small number of cases was the empyema caused by rupture of a pulmonary abscess. Streptococcal infections were more numerous than any other infection. Typical complications occurred in 59 cases, nearly 60 per cent. of which ended fatally. Pulmonary and pleural complications on the opposite side were noted in more than 12 per cent. Nine patients, of whom five recovered, were treated by puncture, but the operation mainly used was subperiosteal resection of a rib, or intercostal incision, and open drainage. Local anaesthesia was chiefly employed, and only in a few cases, especially in children, was a general anaesthetic thought desirable. Permanent recovery resulted in at least 76 per cent. of the acute cases ; recurrence ensued in 32 cases (over 11 per cent.). Pain followed the operation in more than 5 per cent., and thoracic deformity in more than 6 per cent. of those who made a permanent recovery. Transient or permanent loss of the working capacity resulted in more than 7 per cent., 10 per cent. showed tuberculous changes in the lung, and 4 extensive bronchiectasis. The mortality among the acute cases was about 17 per cent., and the total mortality 18.6 per cent. The mortality was least between the ages of 6 and 30 years, and very high during the first two years of life.

540 Perinephritic Abscess

L. G. RIGLER and M. H. MANSON (*Amer. Journ. Surg.*, September, 1931, p. 459) classify cases of perinephritic abscess into two groups: those of renal and those of extrarenal origin. Nineteen cases are reported, of which two were renal in origin ; 16 were extrarenal, and one was doubtful. The diagnosis of this condition is extremely difficult, and accounts, to a certain extent, for the high mortality. In the series under review the average time from the onset of symptoms to the admittance into hospital of the patient was 22.5 days. The most common symptoms are chills, fever, malaise, loss of weight, and backache, with, possibly, tenderness in the lumbar region, spasm of the erector spinae group of muscles, and a fullness or bulging posteriorly between the twelfth rib and the crest of the ilium. The average age in the group reported was 32, and in all but one case operative treatment was undertaken. The youngest patient was 2 years old. In this case the original diagnosis was tuberculous hip disease, since the first symptom was an apparent lameness, followed by inability to walk and a tendency to flexion of the right thigh. An *x*-ray examination is of considerable value in diagnosis ; it was used in eleven cases of the series. An obscuration of the psoas muscle shadow with a loss of kidney outline was observed ; this was due, probably, to infiltration and oedema of the fatty corpuscles. Upward displacement of the diaphragm, and evidence of displacement of the colon, may also be observed. Scoliosis of the lumbar spine was present to a slight degree in four cases. The *x*-ray signs are frequently absent, or doubtful, up to ten days after the onset of symptoms ; they are almost always present within fourteen days. Out of the 19 cases under review, 15 were treated by lumbar drainage, one by drainage following appendicectomy, and two by nephrectomy ; all the patients made good recoveries. The remaining patient died from a uraemia abscess, which was found at the post-mortem examination.

541 Perforated Duodenal Ulcer

V. PAUCHET (*Rev. de Chir.*, September, 1931, p. 473) emphasizes the importance of early diagnosis of acute duodenal ulcer before it has had time to perforate, in order that operative treatment may be given as quickly as possible. Before perforation, there is usually a history of indigestion and general disorder of varying severity ; palpation of the abdomen reveals a localized muscular contraction of the abdominal wall. The symptoms which show that perforation of the ulcer has taken place are unmistakable: a sudden violent pain in the epigastrium or in the right hypochondrium ; rigidity of the abdomen on palpation ; loss of the liver dullness ; and the general signs of shock. When these indications are present, the operation must be performed without delay. The condition occurs most frequently in men between the ages of 25 and 45 who have a history of intermittent dyspepsia. The prognosis is very grave ; if the operation is delayed beyond twenty hours death occurs in 90 per cent. of cases, but when an operation is performed within the first six hours after the perforation, 90 per cent. of the patients recover if the correct technique is followed by the surgeon. Local anaesthesia is most satisfactory, and gives the best results. In cases where the perforation is small, suture

suture is the operation of choice, but when the perforation is large, a gastro enterostomy must also be performed An anterior anastomosis is advised, and drainage of the peritoneal cavity is usually necessary Jejunal ulcer occurs as a late complication in 3 to 4 per cent of cases where a gastro enterostomy has been performed The only treatment in these cases is by an extensive gastrectomy, which is a severe and prolonged operation

542 Bilharzia Infestation of the Renal Pelvis

A DE LUCA (*Arch Ital di Urol* September, 1931, p 74) records the first case on record of bilharziosis of the renal pelvis The patient was a man aged 27, who after serving as a soldier at Leros in Greece underwent ureterolithotomy for ureteral calculus and nephrostomy The operation was followed by the formation of a fistula and rise of temperature, for which a second operation was performed three years after the first, the diagnosis then being subacute pyelonephritis On removal of the kidney fibro lipomatous changes were found in it, together with a papillomatous appearance of the renal pelvis, which revealed the characteristic ova of bilharzia Recovery ensued

543 Epithelio-sarcoma of the Gall-bladder

Malignant tumours of the gall bladder of mixed epithelio-sarcomatous structure are of exceptional occurrence, and only one case has hitherto been reported (by Landsteiner in 1907) A KLEINKNECHT, V NESSMANN and C OBERLING (*Bull de l Assoc Franç pour l Étude du Cancer* July 1931, p 476) record another case of this nature in a woman, aged 69 The condition was acute, the patient dying about nine weeks after the onset of symptoms Nineteen days before death, a very large gall bladder was removed The tumour proved to be a fusiform cellular sarcoma, infiltrated in many parts by epithelioma The authors believe that there had not been a change of the sarcoma to an epithelioma, but that the two growths, though intimately connected, were distinct and had evolved simultaneously with a predominance of the sarcomatous elements The liver was studded with similar metastatic nodules, and evidences of carcinomatous peritonitis were noted Simple sarcoma of the gall bladder is also extremely rare The cases reported show that these neoplasms attack especially aged women, that the gall bladder becomes enormously enlarged, and that the growths have a tendency to give rise to metastases, especially in the liver Various types have been noted, the most common being the fusiform celled variety

544 Fracture of the Acetabulum

G LECCHESE (*Arch Ital di Chir* August, 1931 p 719) records with skiagrams, six cases of fracture of the acetabulum In one case the fracture extended into the ilium without dislocation of the femur, in four the fracture was limited to the base of the acetabulum, and in three of these the head of the femur entered the pelvis In the sixth case the fracture was confined to the rim, and associated with dislocation In addition to the cases recorded by the author, he has collected references to 170 similar cases Since the introduction of radiography more cases have been recorded, owing to the recognition of the less severe types, and to improvement in treatment, the prognosis of these cases is not so gloomy as it used to be Much depends on the degree of concomitant injury, especially in those cases where the head is driven into the pelvis The injury is usually brought about by falls on the trochanter in some cases there may be possibly a certain degree of friability in the acetabulum The dislocation may be direct or secondary, and is commonest when the rim of the acetabulum is affected In these cases reduction of the dislocation is essential, and great care must be taken to avoid recurrence In the intrapelvic dislocations reduction does not seem to be always necessary, in the author's three cases quite good results were obtained without any attempt at reduction Lecchese discusses the question whether it is advisable to perform an open operation in the intrapelvic dislocations, and concludes that except in special cases this is inadvisable, where the concomitant injuries are serious an open operation is impossible It is these injuries which are the cause of bad results, rather than the dislocation The diagnosis rests ultimately on radiography, but ecchymosis of the scrotum, flattening of the trochanter, tumefaction in the iliac fossa, and diminution of the distance between the anterior iliac spine and the trochanter, as well as between the symphysis pubis and the trochanter, may suggest the nature of the injury

Therapeutics

545 Combination of Digitalis with Ephedrine

As it had been observed that a few patients who received therapeutic doses of digitalis showed untoward effects when small daily doses of ephedrine were given, C A JOHNSON and N C GILLEPT (*Journ Amer Med Assoc* May 16th, 1931, p 1668) assumed that the simultaneous exhibition of the two drugs might cause dangerous results They accordingly performed a series of experiments on dogs to determine this question The drugs employed were ephedrine hydrochloride, digilutea, digitol, and ouabain The results and certain clinical observations showed that such undesirable or even dangerous effects are apt to occur The combined effect of these drugs may be merely a summation effect of two cardiac poisons acting on the irritability or conductivity of the cardiac tissue Death in the dogs was apparently due to sudden cerebral anaemia consequent on ventricular fibrillation The authors conclude that when digitalis is being used in cardiac conditions, ephedrine should be avoided or be given only with extreme caution

546 Oleo-chryso therapy

Since the success attending the administration of bismuth in oily suspensions or solutions has been much greater than in aqueous ones, F LEBEUF and H MOLLARD (*Presse Méd* August 29th 1931 p 1671) suggest that the employment of gold salts in a similar vehicle should be followed by equally better results As in the case of bismuth the resorption and elimination of the salt will be much slower, and, consequently its action much more prolonged moreover, it will be better tolerated The work of other authorities on the use of oily suspensions of gold salts is reviewed The present authors recommend the following suspension solganal B an organic combination of gold discovered by Feldt) 1 gram with oil of nuts 10 c cm An intramuscular injection of 2 c cm of this mixture is given three times a week The injections, if made very slowly, are almost painless, and the results obtained in the treatment of syphilis, tuberculides, cutaneous tuberculosis, and psoriasis have been markedly superior to those by other methods Accidents (mucous and cutaneous infiltrations of gold, albuminuria, icterus) are exceptional The authors are now investigating its use in pulmonary tuberculosis, especially in gold resistant subjects, and in those who tolerate badly the usual gold medication

547 Strophanthin Therapy

F GRÜNBAUM (*Med Journ and Record* October 7th 1931, p 320) advocates the employment of intravenous strophanthin therapy in chronic heart insufficiency as practised extensively with satisfactory results in German clinics by specialists and by general practitioners He believes that in all cases in which digitalis effects an improvement, strophanthin is equally effective It is particularly valuable in those cases which respond insufficiently or not at all, to digitalis and to which it would be unwise to administer digitalis in such large amounts as would be necessary to restore the circulatory function Provided that there has been no digitalis medication for at least forty eight hours previously a single intravenous dose of 0 5 mg is safe but this is best administered in the form of two doses of 0 25 mg given night and morning on the first day and possibly repeated on the second day The single dose of 0 5 mg is then given on the first day, and later every second day

therapeutic result. If dehydration and the reduction of oedema proceed too slowly, diuresis can be promoted by combining intravenous injections of salyrgan with the strophanthin. While by this means alone, rather than by the internal digitalis medication, can the optimum therapeutic effect be obtained in severe cases of cardiac decompensation, the method is also said to be of value in milder grades of cardiac insufficiency, since the capability of precise dosage of strophanthin is greater than with digitalis preparations.

548 Indications for Follicular Hormone Therapy

W. SCHOELLER, M. DOHRN, and W. HOHLWEG (*Amer. Journ. Med. Sci.*, September, 1931, p. 326) discuss the chemistry and action of the follicular hormone, and suggest various methods of administering it. Animal experiments appear to justify its being given by the mouth in human patients. Climacteric changes form the chief indication for its use; it was also found to benefit conditions arising from the partial or complete artificial suppression of ovarian function. The relief of vasomotor disturbances is most important, but cutaneous manifestations, intestinal symptoms, and arthritic conditions are also alleviated. Mental changes, especially the frequently occurring psychic depression, are also benefited owing to the generalized tonic effect of the hormone. Menstrual disorders are an indication for this treatment; the hormone has been proved capable of re-establishing a regular menstrual cycle. The follicular hormone alone will fail to produce those effects which depend on its association with the corpus luteum hormone. It is contraindicated in cases of primary amenorrhoea due to complete absence of development of the sexual organs, and in cases of amenorrhoea secondary to such conditions as advanced pulmonary tuberculosis and cachexia.

549 Iodine in Exophthalmic Goitre

W. O. THOMPSON and PHEBE K. THOMPSON (*Arch. Int. Med.*, September, 1931, p. 351) record observations upon the development of refractoriness to iodine in exophthalmic goitre. Contrary to the prevailing impression that the nervous manifestations are brought under complete control while iodine is being administered in excess, irrespective of the basal metabolic rate, notes of cases are given in which the patients after a marked initial response to this treatment became completely refractory to it. One patient, after showing a remission, became completely refractory to a dose of 6 mg. of iodine daily, while four others became partially so during its prolonged administration in doses of from 6 mg. to 250 mg. daily. In four out of the five the refractoriness disappeared within twenty-four days when the iodine was omitted. One patient who was operated upon, when the metabolism was rising rapidly during continuous iodine administration, died about forty hours afterwards from a typical post-operative crisis, which was indistinguishable from those previously seen in patients to whom no iodine had been given. These reactions of refractoriness appeared to be more characteristic of severe than of mild cases. In severe cases the authors believe that an operation is indicated as soon as a maximum reduction in the basal metabolic rate occurs. When this is markedly increased during the administration of iodine, the operation should be postponed until three or four weeks after the suspension of iodine treatment, the patient resting in bed, to allow the refractoriness to disappear. The iodine administration is resumed before the operation.

550 Treatment of Chronic Myelogenous Leukaemia

R. G. GILES (*Radiology*, October, 1931, p. 764) emphasizes the importance of treating the leukaemic process in chronic myelogenous leukaemia, as well as the secondary anaemia. In addition to dieting, general ultra-violet treatment, the administration of iron and arsenic, and the employment of blood transfusion, irradiation of the spleen, chest, and the long bones is recommended as being one of the most hopeful procedures in securing and prolonging remissions. The author has noted on more than one occasion that, even after the disease has finally become refractory to the longer *x*-ray wave-lengths, the more penetrating short wave-length rays can be relied upon to give further remission from the symptoms. Splenectomy does not modify the evolution of the disease, or alter the leucocytosis, but irradiation brings the blood formula towards the normal for longer or shorter periods. The frequency of such irradiations should be controlled by leucocytic determinations, the results of which should not be allowed to fall below 30,000 per c.mm. The smallest effective dose should be determined, and then be used until repeated observation indicates that a heavier form of irradiation has become necessary.

Anaesthetics

551 Pre-operative Hypnosis in Children

MARY E. BOTSFORD (*Anesthesia and Analgesia*, September–October, 1931, p. 221) advocates the oral administration of sodium iso-amyl-ethyl-barbiturate to children as a pre-operative hypnotic. The advantages of the drug in adults having been fully established, it was given to 50 children between the ages of 2 and 14, in doses of 1.5 to 9 grains according to age, weight, blood pressure, and the general physical condition. Except in one case of oesophageal stricture (when it was introduced through the gastrostomy feeding tube) it was administered in capsules or solution by the mouth half an hour before the operations; these included tonsillectomies, mastoidectomies, cystoscopies, orthopaedic operations, sinus irrigations, and circumcisions. No other preliminary hypnotic was employed, and the routine dose of morphine and atropine was omitted. Nitrous oxide induction and ether anaesthesia were used for the tonsillectomies and nitrous oxide and oxygen for other operations. Blood pressure observations showed a systolic fall of 2 to 9 mm. in 39 cases, and a rise of 4 to 12 mm. in 11 cases. Transitory acidosis occurred in two instances in which pre-operative alkalization had not been effected. From these observations the author concludes that the drug is a safe pre-operative hypnotic for children, and that it is more effective than opium derivatives in preventing fear, with its immediate effects upon the induction and depth of the anaesthesia and upon later morbidity.

552 Percaine Anaesthesia

E. THOMSEN (*Ugeskrift for Laeger*, September 10th, 1931, p. 922) reviews the first 50 cases in his hospital in which percaine was used as a regional or local anaesthetic. The advantages it possesses over novocain-suprarenin include an almost instantaneous and protracted effect, comparative cheapness, and the fact that it has not to be supplemented by adrenaline. But percaine is said to be about five times as toxic as cocaine, as well as being ten times as effective as an anaesthetic. On account of its toxicity, care must be taken not to inject it into a vein. The ages of the first 50 patients ranged from 14 to 84, and the amount of the 1 in 1,000 solution injected ranged from a minimum of 4 c.cm. to a maximum of 97 c.cm. In the case of a man, aged 59, operated on for hernia, and given 54 c.cm. of a 1 in 1,000 solution of percaine, alarming and sudden collapse ensued, with cyanosis and great air hunger. Stimulants were given, but for the rest of the day he looked very ill. Though this case did not end fatally, the author considers it an indication for great caution in the use of percaine, and he does not recommend it for operations on goitres, the facilities for an unintentional intravenous injection of the drug in this case being too great.

553 P. KÜHNEL (ibid., p. 924) records a fatal case of percaine poisoning. The patient was a girl, aged 13, suffering from Little's disease, on whom an operation in the popliteal spaces was to be performed under local anaesthesia. Altogether 110 c.cm. of a 1 in 1,000 solution of percaine were injected into the limbs. The operation had only just been started when convulsions set in, and

marked cyanosis and respiratory disturbances Death occurred a little more than an hour after the injection It should be noted that the patient suffered from well-compensated heart disease, and it was on this account that a local, instead of a general, anaesthetic had been given The author concludes that, as percaine has shown itself to be superior to other anaesthetics in such important ways, his fatal case does not warrant the abandonment of this drug in those spheres in which it has given satisfaction

554 S WITH (*ibid*, p 925) records the case of a woman, aged 43, suffering from a goitre, for which she was to be operated on under local anaesthesia ; 70 c cm of a 0 5 per 1,000 solution of percaine suprarenin (3½ cg of percaine) were injected in four different places Most alarming symptoms, including cessation of the respiration, dilatation of the pupils, and cyanosis, began while the last portion of the drug was being injected, and it is possible that some of it escaped into a vein Although there were no permanent sequels to this incident, and the patient was well next day except for some pyrexia, local anaesthesia was not again attempted, and she left hospital without a further attempt at operation

555 Spinal Anaesthesia in Abdominal Emergencies

J S GAREISO (*Rev Med Latino Americana*, August, 1931, p 1617) records his observations on 41 cases in patients aged from 15 to 73 of acute abdominal emergency, including appendicitis, with or without peritonitis, strangulated inguinal hernia, haemorrhagic pancreatitis, retroperitoneal haematoma, ruptured tubul pregnancy, perforation of the uterus, and fracture of the pelvis with extraperitoneal rupture of the bladder The anaesthetic mixture used was stovaine and morphine All the patients made a good recovery The results showed that spinal anaesthesia can be employed in any case of abdominal emergency, that arterial hypertension is no contraindication to its use, that no other method produces such complete anaesthesia without any shock, and that the toxic effect on the liver, lungs, kidneys, other organs, and general parenchyma is very slight

Obstetrics and Gynaecology

556 Friedman's Modification of the Aschheim-Zondek Test

M DAVIS and ELISABETH W WALKER (*New England Journ of Med*, September 17th, 1931, p 566) report their results obtained with the Friedman modification of the Aschheim Zondek test, they found this modification reliable and more simple than the original technique One intravenous injection of 10 c cm of the first voided morning urine is made into the marginal ear vein of a rabbit The ovaries of an isolated unmated rabbit contain no corpora lutea or corpora haemorrhagica, since the rabbit does not ovulate spontaneously, but only after coitus After the injection of the urine of a pregnant woman (which in its biological effects simulates those of the anterior lobe of the pituitary) the ovary of the rabbit quickly responds by the formation of corpora lutea or corpora haemorrhagica The result can be read at the end of twenty-four or thirty-six hours, instead of at the end of 100 hours as in the original test The development of methods for concentrating the hormone from the urine will probably enable a diagnosis to be made at even shorter intervals This modified test has been used in 308 cases, and has proved to be delicate and accurate It can also be employed for the differential diagnosis in the case of pelvic masses or neoplasms, and in menstrual irregularities of various types Early pregnancy can be ruled out in cases where some form of instrumentation of the uterus is to be undertaken Death of the ovum may be diagnosed, and it is possible also to determine the presence of active placental tissue in cases of incomplete abortions, of hydatidiform mole, and of chorion-epithelioma.

557 Hysterectomy for Large Gangrenous Polyps of the Uterus

J VILLAR (*Journ de Méd de Bordeaux*, September 20th 30th, 1931, p 809) draws attention to the fact that in the course of one year two patients were admitted to the Hôpital Boursier with very large gangrenous polyps of the uterus Both were operated upon by vaginal polypectomy without any great difficulty, yet both succumbed in twenty-four to forty eight hours to a fulminating septicaemia Villar discusses the advisability of employing the vaginal route in these cases when the polyps are of such a size that they fill the vagina, and do not permit the examining finger to reach the pedicle Vaginal polypectomy is usually the operation of choice, since it seems more natural to deliver a descending tumour in that manner Moreover, it appears to be wiser to perform as limited an operation as possible on an already debilitated patient Further, to limit a septic operation to a septic area would appear to give the patient more chance of resisting septicaemia Statistics, however, reveal that vaginal polypectomy is far from being a benign operation, the mortality ranging from 50 to 60 per cent , death generally occurs from twenty four to forty-eight hours after the operation The uterus, damaged by the operator, affords suitable lodging for bacteria, which multiply in the genital passages To improve these lamentable results Villar suggests that the following principles should be recognized (1) complete extirpation of the septic focus , (2) adequate drainage , and (3) prevention of loss of blood These requirements are only fulfilled by total hysterectomy, and Villar maintains, consequently, that this method of treatment for gangrenous polyps gives the optimum results

558 Uterine Suspension

R W LAGERSEN (*Surg , Gynecol and Obstet* , October 1931, p 545) criticizes the methods of uterine suspension by shortening the round ligament, and advises the following modification The uterus, grasped with forceps, is drawn upward and forward, and is incised for an inch on the posterior median line, so that two-thirds of the incision is below the round ligaments A subserosal dissection is then made bilaterally, and the round ligament is grasped bilaterally and drawn medially The two ligaments are then opposed, and adjusted for tension and obviation of ante and retro-flexion The suspensive mechanism, having thus had any fault corrected, is apposed by suturing the ligaments to each other and to the uterus The serosal incision is then closed by a subserosal continuous suture The serosa is sometimes difficult to separate , an injection, before incision, of normal saline solution in the middle line and laterally beneath it, forces away the serosa, and simplifies dissection The advantages claimed for this technique are : there is no break in the peritoneal continuity, except at the serosal incision , the suspension is likely to maintain its integrity , and there is no opportunity for herniation, either through a loop of the round ligament or a rent in the broad ligament.

559 Uterine Fibromata and Arterial Hypertension

M VASSITCH (*Gynécol. et Obstet* , August 1931 p 128) discusses the question whether uterine fibromata and arterial hypertension have a common causal factor To further the investigation he undertook a comparison between the arterial tensions of women known to have uterine fibromata, and a similar number of chance patients who were free from fibromata The arterial tension was measured by the Vaquez Laubry apparatus and the figure 15 was taken as the normal limit Among 38 patients with uterine fibromata 21 were found to have a raised tension (before operation which varied from 18 to 28, and there was only a slight alteration subsequently Among the 38 control patients 6 had a tension raised to between 17 and 27 The frequency of the coexistence of uterine fibromata with arterial hypertension appeared to be confirmed Numerous hypotheses have been advanced to demonstrate a causal relationship between the two conditions, such as. (1) peripheral "barrag due to the

mechanical action of compression of the tumour; (2) compression of the uterus influencing the cardio-vascular circulation; (3) a neuro-arthritic diathesis; (4) endocrine imbalance; and (5) haemorrhage. Vassitch considers it necessary to envisage the frequent coexistence of these conditions as an evolutionary coincidence, the two diseases having analagous affinities.

560 Treatment of Menorrhagia

B. F. SCHREINER (*Radiology*, October, 1931, p. 796) discusses the treatment of myopathic and thrombopenic menorrhagia, and records a series of 73 cases in which radium and *x* rays were employed. In 68 cases the bleeding was myopathic in origin; 3 patients were treated solely by *x* rays, 55 by radium alone, and the remainder by a combination of these methods. Seven patients were lost sight of immediately after the treatment, but all the remainder were found to have been cured. The remaining five cases were diagnosed as thrombopenic purpura haemorrhagica. Four were controlled by *x*-ray applications alone, but the remaining one had to undergo splenectomy three months after treatment. Schreiner insists on the importance of a thorough blood examination in the diagnosis of this condition in all cases where no demonstrable causes are discoverable. Details are given of the technique of the treatment; little, if any, disturbance in the form of nausea or vomiting resulted.

Pathology

561 The Etiology of Tsutsugamushi Disease

N. OGATA (*Zentralbl. f. Bakt.*, October 1st, 1931, p. 249) gives a short description of the tsutsugamushi or kedani disease of Japan, and cites evidence that it is caused by an organism belonging to the Rickettsia group. The disease is confined to certain provinces; it occurs in the summer and autumn months; it is most frequent in low-lying territory subject to flooding; and it follows the bite of the akamushi mite *Trombicula akamushi* (Brumpt). The main symptoms appear about a week after the bite, and consist of fever, local swelling at the site of the puncture wound, enlargement of the lymph glands and spleen, and a rash. The case mortality rate is about 40 per cent. The disease can be experimentally reproduced by the intracutaneous inoculation of Japanese monkeys with the patient's blood. Rats and guinea-pigs can be used, but the symptoms in them are less characteristic. The author has, however, found that the causative organism can be successfully maintained in the laboratory by passage every two or three weeks through the rabbit's testicle. Over 150 transfers of the organism have been made by this method during the past four years, without any evidence of a decrease in virulence to monkeys. An orchitis results with the production of swelling, induration, and small haemorrhages. Microscopical examination of the testicle reveals the presence of small Gram-negative, often bipolar-stained, coccobacilli, 0.7 to 1.7μ long and 0.5 to 0.7μ broad. These organisms cannot be grown in the usual culture media, though in tissue cultures they may remain alive for four weeks. On account of these properties, its non-filterability, and its carriage by arthropods, the author considers the causative organism to belong to the Rickettsia group, and suggests the name *Rickettsia tsutsugamushi*.

562 Functions of the Renal Glomerulus

D. L. WILBUR (*Proc. Staff Meetings Mayo Clinic*, July 29th, 1931, p. 449) gives reasons for concluding that the anatomical evidence, considered in the light of present physiological knowledge, is overwhelmingly in favour of the theory that the glomerular function is based on a filtration process. The kidneys are concerned with keeping the composition of the blood plasma more or less constant. The glomerular basement membrane, although appearing to be directly continuous with the intertubular and capillary membranes of the kidney, differs somewhat in appearance and also chemically in several important respects. The marked changes it undergoes in hypertension and nephritis are in large part characteristic of the disease. The intermittency of the blood flow through the individual glomeruli is not related to the pulse, or to any extrarenal factors, but is under the capillary-constricting influence of the splanchnic nerves which is overwhelmed from time to time by anoxaemia. No anatomical evidence in support of a secreting function has been obtained in the case of the glomeruli, and the only cells in them which could possibly have a secretory function are so few, so closely similar to the parietal cells of Bowman's capsule, and so scantily provided with cytoplasm that secretion can hardly be regarded as possible. The author cites various physiological conditions, such as the production of diuresis, to strengthen further his conclusion, and his belief in the inseparability of the glomerulus and the tubule as a functioning unit.

563 Cultivation of Tubercle Bacilli from the Blood

A. SAENZ (*C. R. Soc. de Biologie*, September 18th, 1931, p. 1455), following Loewenstein's technique, has made blood cultures on 300 patients, and has succeeded in cultivating acid-fast bacilli on eighteen occasions. In only seven of these cases did macroscopic colonies appear; in the other eleven the bacilli were detected by microscopical examination of scrapings of the surface of the culture, though on subculture on to fresh medium it is stated that nearly all produced visible colonies. How many of the strains were properly studied is not recorded, but one of them is said to have been of the avian type, and one to have possessed characters intermediate between those of a tubercle bacillus and a saprophytic acid-fast bacillus. The author has no great opinion of Loewenstein's Congo red medium, which not infrequently becomes contaminated, and prefers to use Lubenau's or Petragnani's medium. On the other hand, he is impressed with the importance of strictly following Loewenstein's directions with regard to the treatment of the blood clot. It is concluded, however, that the method offers too many difficulties to be of value in routine diagnosis.

564 Equilibrium Between the Cerebro-spinal Fluid and Plasma

F. FREMONT-SMITH *et al.* (*Brain*, September, 1931, p. 303) record a series of ninety-four comparative freezing-point determinations on simultaneous samples of blood serum and cerebro-spinal fluid in seventy-three patients. In eight patients with various kinds of meningitis twenty-three determinations were made; sixty-five of the non-meningitic patients, and nine of the meningitic had been fasting for nine hours or more before the samples of cerebro-spinal fluid and blood were obtained. In forty-four of the seventy-one comparative determinations the freezing point of the cerebro-spinal fluid was within 0.005° C. of that of the serum. In only fifteen instances was the difference in freezing-point depression greater than 0.015°, the greatest difference being 0.037°. The authors conclude that this increase in the human cerebro-spinal fluid is ordinarily in osmotic equilibrium with the blood serum, thus confirming the views of Mestrezat and Teschler. The occasional appreciable differences which may be noted in the freezing-point depression of these two fluids are probably to be explained by the occurrence of a latent period before changes in the composition of the blood are reflected in the spinal fluid. Even in the case of acute purulent and tuberculous meningitis, where rapid changes in the blood composition may be expected, six of the twenty-three comparative determinations showed identical freezing points within 0.005°, while in only [illegible] instances was the freezing-point difference between [illegible] serum and cerebro-spinal fluid greater than 0.025°. In each of these ten instances, moreover, the blood serum was hypertonic to the spinal fluid, which is what would be expected if the patient was being rapidly dehydrated by sweating and vomiting, and the spinal fluid had not reached equilibrium with the concentrated blood.

OSTOMALT presents

Vitamins A. B, C, and D in the form of a readily assimilable and most appetising preparation. Its vitamin potency has been rigidly standardised. For convalescent or otherwise debilitated adults and children, even for those suffering from severe anorexia, Ostomalt serves as an ideal tonic food, stimulating the appetite for other kinds of nourishment.

IN HALF-POUND AND ONE-POUND JARS

A trial jar of Ostomalt will be sent to any medical practitioner, on request to GLAXO LABORATORIES, 56. OSNABURGH STREET, LONDON, N.W.1.

Colloidal Calcium with OSTELIN vitamin D

CHILBLAINS

For this condition, a highly experienced School Medical Officer has described subcutaneous injection of Ostelin Colloidal Calcium as a specific treatment.

Extensive clinical tests have shown it to be equally valuable as a prophylactic.

Pain and irritation subside in many cases after the first injection. this method of administering Vitamin D and calcium ensuring their rapid and prolonged effect on the capillary circulation.

BED DAMPNESS BANISHED . . . .

An important health factor, particularly at this time of the year when coughs, colds, and flu are so prevalent, is sound healthy sleep.

Thermega Electric Blankets and Pads are made for this specific purpose.

Laid flat on the bed and switched on an hour before retiring, the Blanket airs and warms the bed to body temperature. The Pad ensures LOCAL regulated heat which may be maintained as long as desired.

Both are controlled by an ordinary wall switch (any voltage, 100—250); overheating is eliminated by special thermostatic control; current costs less than a farthing an hour.

Blankets from £3 3s., Pads from 31/6, Heating Blankets for Doctors' couches from £7. Special appliances for pneumonia, operations, etc., to order.

Further details supplied immediately on request.

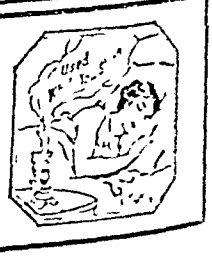
Vapo-Cresolene Est. 1879

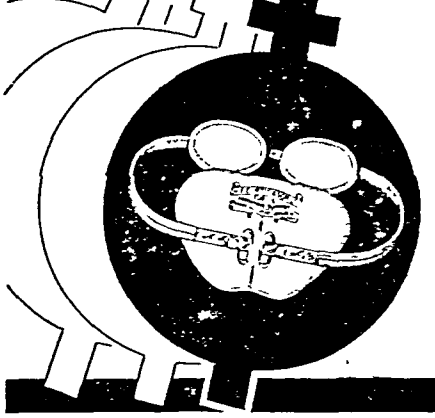


Sold by all Chemists

Write for descriptive Booklet No. 140.

ASTHMA

There are certain types of chronic asthmatics who require relief of their paroxysms. While adrenaline is generally effective, it must be given hypodermically, and its action is short lived. Vapo Cre-olene (specially prepared cresols of coal tar), vaporized in the bedroom at night, will give the desired relief. The patient is not disturbed as he breathes the medicated air of the bedroom.



This antiseptic vapour is particularly effective in bronchial ailments accompanied with cough and difficult breathing—as bronchitis, whooping cough, spasmodic croup.

ALLEN & HANBURYS, LTD. :: :: Lombard Street, London, E.C.3.

Freedom of Movement-

The principle of the Curtis Abdominal Support Model No. 1 is that of anterior-posterior pressure, and is the only support that gives direct abdominal uplift without cramping or binding the hips, assuring the patient freedom of movement at all times.

ST. ANDREW'S HOSPITAL

FOR MENTAL DISORDERS,

NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or who wish to prevent recurrent attacks of mental trouble, temporary patients, and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms, with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombieres treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres at Llanfairfechan, amidst the finest scenery in North Wales. On the North West side of the Estate a mile of sea coast forms the boundary. Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing beach on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for hard exercise such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 5 Northampton), who can be seen in London by appointment.

COURT HALL, KENTON, EXETER,

SOUTH DEVON.

For the care and treatment of Ladies suffering from Mental Disease. Limited to eight patients. Telephone: Starcross 19

CLIFFDEN, TEIGNMOUTH, in connection with Court Hall, for early and convalescent cases. Cliffden is a large well appointed house, with lovely views of the South Devon coast. It is beautifully situated in grounds of 19 acres. The gardens are very attractive, and there is a private road to the beach.

Resident Physicians: BERTHA M. MULES, M.D., B.S.; ANNIE S. MULES, M.R.C.S., L.R.C.P.
Telephone: Teignmouth 289.

TYKEFORD ABBEY, NEWPORT PAGNELL,

BUCKS.

FUNCTIONAL NERVOUS DISORDERS, MEDICAL & CONVALESCENT CASES.

An Approved Nursing Home for reception of Female Cases under the Mental Treatment Act.

The Home is a Mansion of Historical interest, standing in 9 acres of garden and grounds and is situated 14 miles from Northampton, and 12 miles from Bedford on the main London to Northampton Road, fifty miles from London. Both sexes are accommodated. Electric Therapeutic Treatment is used extensively in suitable cases. Radiant Heat, X Ray, and Ultra-violet Light. Diathermy and Foam Baths. Billiards, tennis, etc. Fees from five grs per week.

Apply, Dr. D. E.-M. DOUGLAS MORRIS. *Telephone*: Newport, Pagnell 121.

HAYDOCK LODGE,

NEWTON-LE-WILLOWS, LANCASHIRE.

'Phone: 11 Ashton in Makerfield.

For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES either voluntarily or under Certificate. Patients are classified in separate buildings according to their mental condition.

Situated in park and grounds of 400 acres. Self-supported by its own farm and garden in which patients are encouraged to occupy themselves. Every facility for indoor and outdoor recreation. For terms, prospectus, etc., apply MEDICAL SUPERINTENDENT.

THE COPPICE, NOTTINGHAM.

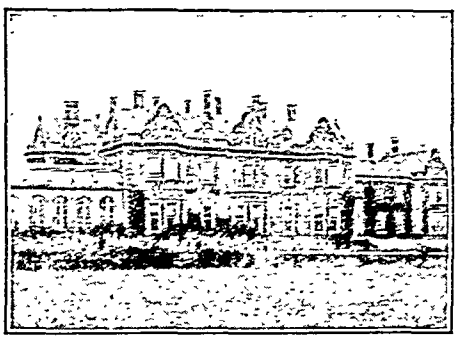
HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an elevated site a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary and Temporary Patients received.

Tel.: 64117. *For terms, etc., apply to the Medical Superintendent.*

THE RESIDENTIAL TREATMENT OF ALCOHOLISM & DRUG ADDICTION

RENDLESHAM HALL



(Postal Address)—WOODBRIDGE, SUFFOLK.

Rendlesham Hall, which is open to receive patients, is essentially a Sanatorium. Its daily life and routine are that of an ordinary comfortable holiday or health resort, or of a large country house. Each patient has all the privileges of a guest consistent with the prescribed medical treatment.

Rendlesham Hall has 45 bedrooms, and about 450 acres of gardens and park. It has also a private nine-hole golf course, tennis and croquet lawns, and bowling green.

Illustrated booklet, giving particulars as to terms, etc., can be had on application to the RESIDENT MEDICAL SUPERINTENDENT.

Telegrams and Telephone: Wickham Market 16. *(Toll Call from London.)*

RENDLESHAM HALL.

To those desiring to be near London—

CITY OF LONDON MENTAL HOSPITAL, DARTFORD, KENT.

Ladies and Gentlemen received for treatment under certificates and without certification, as either VOLUNTARY or TEMPORARY PATIENTS, at a weekly fee of TWO GUINEAS and upwards.

RUTHIN CASTLE, NORTH WALES

REDUCTION OF FEES

In view of the present economic position, the inclusive fees at Ruthin Castle, formerly from 17 guineas a week, have been reduced to from 15 guineas a week.

The fees include medical attendance, all scientific investigations that may be needed, such as analyses, bacteriological cultures, the ordinary x-ray examinations, and electrocardiograph readings; all treatment that may be prescribed, such as special diets, insulin, artificial sunlight, electrical treatment, baths, massage, nursing; medicines or vaccines, board and lodging.

The only extra charge is that for a complete alimentary x-ray examination, or for x-ray therapy.

Many people who would go abroad for health will not do so this winter. All the usual forms of treatment are given at Ruthin Castle. The climate is mild. The annual rainfall is 30.5 inches, that is, less than the average for England. There is central heating throughout. Should the accommodation in the Castle not prove sufficient, comfortable rooms can be obtained near by for those undergoing treatment.

Address—THE SECRETARY, Ruthin Castle, North Wales. *Telegrams*: CASTLE, RUTHIN. *Telephone*: RUTHIN 66.

Send your Patient to a British Spa

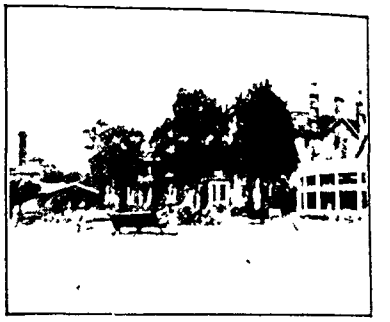
BRITISH SPAS *are BEST*

NO Country in the world offers such a variety of natural mineral waters and Spa treatments as are available in your own Country. The medical profession is assured of individual attention being given to their patients at the hands of trained staff.

Hotel tariffs are cheaper during the winter, and special diet can be arranged without extra charge.

Handbook and tariff charges with list of accommodation will gladly be sent on application to the Hon. Secretary, British Spas Federation, Pump Room, Leamington Spa, or the Manager of any of the Spas here mentioned.

NEURALGIA AND NEURITIS



Few diseases cause so much suffering as nerve pains, such as sciatica, trigeminal neuralgia, brachialgia, and intercostal neuralgia.
This group of diseases is rapidly and effectively treated at Pistany (Czechoslovakia) by volcanic mud—driven to the surface by hot sulphur springs. Statistics show that *of 100 patients, only less than 5% do not respond to* the treatment—30% are completely relieved and 65% are considerably improved.
Pistany RADIO-ACTIVE Mud Packs and Compresses are simply and easily applied. This treatment may be successfully combined with other physiotherapeutic methods.

SUNNY WORTHING

THE SUSSEX RIVIERA WINTER RESORT *'TWIXT SEA AND DOWNS*

A sheltered nook in one of the public parks

Occupying a sheltered position on the South Coast, Worthing enjoys a maximum of sunshine and an astonishing immunity from snow and gales. The rainfall is much lower than that of towns situated in the south-western counties. In addition, it is delightfully level and affords just those conditions so necessary for persons suffering from heart or chest complaints. Several delightful parks overlook the sea and afford sheltered nooks and corners where the most delicate can enjoy warm sunshine with a complete absence of winds or draughts.

The town is sufficiently large and self-contained to provide all the facilities that visitors may reasonably expect, though the aim of the local authority has been to ensure that restful and quiet atmosphere so necessary to the seeker of health. An attractive programme has been arranged for the Pavilion winter season.

There are excellent facilities for golf, hunting, horse-riding, badminton, tennis, and other sports.

The journey from London is accomplished in 80 minutes by through express trains.

Copies of the OFFICIAL GUIDE, HOTEL REGISTER, and WINTER PROGRAMME will be forwarded upon application to the Town Clerk (M.J.), BEACH HOUSE, WORTHING, SUSSEX.

TORQUAY

ENGLAND'S MARINE SPA

TREFRIW CHALYBEATE WELLS

Established over 70 years.

The richest Sulphur-Iron waters known, containing Iron as Ferrous-Sulphate, maximum dose only one ounce. Wonderfully efficacious for Rheumatoid Arthritis, Rheumatism, Sciatica, Neuritis, Anaemia, and Kindred Ailments.

SPA CURE AT HOME.

The Waters are scientifically bottled in perfectly natural Spa condition, without alteration or manipulation, and may be prescribed to patients at home just as beneficially as at the Spa. The remarkable efficacy of the home treatment, which is a very important feature of this Spa, cannot be too strongly emphasized, and is well attested by eminent medical authority. Full particulars and sample of the Waters post free from MANAGER, Trefriw Wells, Trefriw, N. Wales

"THE VICTORIA," BRITISH SANATORIUM

DAVOS-PLATZ, SWITZERLAND.

ALTERED AND MODERNISED IN SUMMER 1930.

PUBLIC HEALTH DEPARTMENT.

BOOTH HALL HOSPITAL.

APPOINTMENT OF AN ASSISTANT MEDICAL OFFICER.

The Public Health Committee invites applications from qualified Medical Men for the position of Assistant Medical Officer at the Booth Hall Hospital for Children (750 beds), Charlestown Road, Blackley, Manchester.

Every applicant must be a registered Medical Practitioner and unmarried.

Preference will be given to applicants with previous Hospital experience.

The Hospital is a recognised Training School for Nurses and is equipped with all modern hospital requirements.

Salary £243 10s per annum, with board, residence, and laundry in addition, subject to the terms and conditions of the Manchester Corporation Grading Scheme. No bonus.

The appointment will be made, in the first instance, for a period of six months. The successful candidate, however, will be eligible for reappointment for a further period of six months at the end of that period.

Every application, stating fully the training, qualifications, and experience of the candidate, and his age, with copies of three recent testimonials, and endorsed on the envelope "Assistant Medical Officer, Booth Hall Hospital," must be addressed to the Medical Officer of Health, Civic Buildings, 1, Mount Street, Manchester, only, and not to members of the Committee or Council, and must be received by him not later than Monday, December 21st.

The candidate appointed will be required to commence duty as soon as possible after January 17th, 1932, to devote the whole of his time to the duties of the position, to pass a medical examination, to contribute to the Corporation Superannuation Fund, and to execute the Deed of Service.

Canvassing in any form, oral, or written, direct or indirect, is prohibited.

Town Hall, Manchester. F. E. WARBRECK HOWELL, Town Clerk.
December 7th, 1931.

University of the Witwatersrand, JOHANNESBURG.

SENIOR LECTURER IN ANATOMY.

Applications are invited for the above post from medically qualified candidates. The teaching embraces Histology in addition to Gross Anatomy.

The salary at present offered is £516 per annum, rising by annual increments of approximately £26 to £726 per annum, but these rates may be affected by the financial position of the country, and candidates who have applied will be informed of any reduction which may take place.

Participation in the University Teachers' Provident Scheme is compulsory. This scheme provides for a contribution by the members of 6 per cent. of their basic salary (£450—£25—£650), the fund contributing the same amount. A higher commencing rate of salary may be approved in the case of a candidate possessing special qualifications or experience.

An amount of £60 will be allowed for travelling expenses, and half salary paid from the date of embarkation to the date of arrival in Johannesburg.

The appointment, which is a full time one, is subject to all the conditions and rules now in force, and duty is to be assumed as soon as possible after appointment, which will be communicated by cable.

Further particulars as to the conditions of service may be obtained from the Secretary, Office of the High Commissioner for the Union of South Africa, South Africa House, 73, Strand, London, W.C.2, from whom forms stating the particulars required may be obtained.

Applications, in duplicate, accompanied by testimonials, should reach the High Commissioner's Office not later than Jan. 15th, 1932.

Applications are invited for an appointment as PROFESSOR OF PATHOLOGY, MEDICAL COLLEGE, CALCUTTA, and BACTERIOLOGIST to the GOVERNMENT OF BENGAL. Candidates must possess a medical qualification registrable in England, and should have considerable practical experience in Bacteriology and Parasitology and Morbid Anatomy and Histology and experience in teaching these subjects. Age should normally not be more than 40 years. (Applications will be accepted from officers serving under Government in India upon special terms.)

Agreement for three years in the first instance. Pay at rate of Rs 800, rising by annual increments of Rs 50 to Rs.1,500 a month (subject to a reduction of 15 per cent.), plus a Bacteriological allowance of Rs.225 a month, plus overseas pay (for an officer of non-Asiatic domicile) of £50 a month. Provident Fund. Free first-class passage to India. Strict medical examination.

Further particulars and forms of application may be obtained upon request by postcard to the High Commissioner for India, General Department, India House, Aldwych, London, W.C.2. Last date for receipt of applications December 31st.

City and County of Kingston-UPON-HULL.

BEVERLEY ROAD INSTITUTION (HOSPITAL).

ASSISTANT MEDICAL OFFICER (Woman).

The Corporation of Hull invite applications from unmarried or widowed registered Medical Practitioners, under the age of 40 years, for the appointment of Assistant Medical Officer (Woman) at the above named Hospital for a term not exceeding one year, and not renewable.

Salary is at the rate of £300 per annum, together with board, residence, and laundry. The salary is subject to any deduction which the City Council may authorise in connection with economic measures.

The Hospital Section contains 400 beds, and is equipped with X-ray and Ultra-violet Light Departments.

A form of application, together with conditions of appointment and a list of duties, may be obtained from the undersigned, to whom completed applications should be returned not later than 10 a.m. on Monday, December 21st.

Health Department, Guildhall, Hull. N. GEBBIE, Medical Officer of Health.
December 1st, 1931.

Sudan Government.

WELLCOME TROPICAL RESEARCH LABORATORIES, KHARTOUM

Applications are invited for the post of BACTERIOLOGIST at an initial rate of pay of £E 660 or £E 720 per annum (according to age and qualifications), with five or six annual increases to £E 1,080, and thence after three years to £E 1,200. These rates of pay are as the conditions of service are subject to Government rules and regulations from time to time in force. (£E 1 = £1 0s 6d.)

Applicants must be unmarried, and will be expected to take up their duties immediately.

Applications, stating age, degrees, experience (with special reference to Pathology) and names of testimonials, should be sent to the Director, Wellcome Tropical Research Laboratories, Khartoum, Sudan.

Further particulars regarding this post may be obtained on application to the Central Sudan Government, London Office, Wellcome House, Buckingham Gate, London, S.W.1.

City of Birmingham.

DUDLEY ROAD HOSPITAL

GYNAECOLOGIST AND OBSTETRICIAN.

Applications are invited from fully qualified registered Medical Practitioners for the above whole time appointment.

The present Hospital accommodation is 920 beds, divided into Medical, Surgical, Gynaecological, Obstetrical, and Children's Sections. There are completely equipped Pathological and Biochemical laboratories, X-ray, Deep X-ray, Electro-therapeutic, Massage, Ultra-violet Electro-cardiographic and Dental departments. Over 4,000 operations are performed annually.

Candidates for the appointment must have had good experience in these subjects and be Fellows of the Royal College of Surgeons (England).

The salary will be £750 per annum rising by annual increments of £50 to a maximum of £1,000 per annum, and furnished quarters, rations, laundry, and attendance will be provided. The appointment will be subject to the Birmingham Corporation's Superannuation Scheme, to the candidate passing a medical examination, and to one months' notice on either side.

The salary and emoluments above referred to will be subject to (a) a "voluntary abatement" which it has been agreed, for the present, shall extend for one year expiring on December 31st, 1932, and (b) superannuation deductions amounting to 5 per cent.

The officer appointed will be required to pay to the fund to the Council, all fees, allowances, and emoluments (other than the foregoing) received by him. He will also be required to assist in the training of, and lecturing to, nurses.

Further particulars of the appointment may be obtained from the Medical Superintendent, Dr. F. W. ELLIS, at Dudley Road Hospital.

Applications, stating age, experience and qualifications, accompanied by copies of recent testimonials, and endorsed "GYNAECOLOGIST," should be addressed to Dr. ELLIS, and reach him at his office not later than Friday, December 18th.

F. H. C. WILLSHIRE, Town Clerk.

The Council House, Birmingham, Dec. 4th, 1931.

The Radium Institute,

Riding House Street, London, W.1.

Applications are invited for the post of HOUSE SURGEON. Candidates must be fully qualified, unmarried, and of British nationality. The appointment is for a term of six months, and the successful candidate will be required to take up the duties on January 15th, 1932. The salary will be at the rate of £150 per annum, with board, lodging, and laundry. Applications, stating age, qualifications, and experience, with copies of three testimonials, must be received at the Institute later than the first post on December 19th.

THOS. A. GARNETT, Secretary.

Peckham House,

112, Peckham Road, London, S.E.15.

JUNIOR ASSISTANT MEDICAL OFFICER required, male, single, and under 30, for a large private Mental Hospital. Salary £150 per annum with all found. Apply to the Superintendent.

ROYAL ARMY MEDICAL CORPS.

TWENTY-FIVE *permanent* COMMISSIONS *in the* ROYAL ARMY MEDICAL CORPS will be offered in January, 1932. Applications should reach the War Office not later than January 18th, 1932.

Candidates will be selected for Commissions without competitive examination, and will be required to present themselves in London for interview and medical examination towards the end of January. They must be under 28 years of age on February 1st, 1932, and registered under the Medical Acts.

Officers of the R.A.M.C. are liable to serve in any part of the world where British Troops are quartered.

Ample opportunities exist in the Army for clinical professional work, both Medical and Surgical, as well as for the study and practice of Hygiene, Pathology, and all the special branches.

The cost of Post-Graduate study, which is compulsory, is met from Army Funds.

Pay and Allowances.—From £476 to £2,000 a year according to rank and length of service.

Candidates who have held a full-time house appointment in a recognised civil hospital before appointment to a permanent Commission in the R.A.M.C. may, subject to certain conditions, be allowed to count the period of service in such an appointment, up to a maximum of 12 months, as Army service for promotion and increase of pay.

Gratuities on Retirement.—After 7 years' service £1,000.
" 15 " " £2,800.
" 18 " " £3,500.

Current rates of retired pay range from £352 10s. per annum normally earned by a Major after 20 years' service, to £890 per annum, the maximum for which a Major-General is eligible. The rates of pay and retired pay are subject to periodical variation consequent on fluctuation in the cost of living.

Outfit Grant.—An officer on joining receives £50 as outfit allowance.

Marriage Allowances.—Officers of 30 years of age and over who are married are entitled to draw special rates of allowances.

A Voluntary Widows' and Orphans' Fund exists for officers of the Corps.

A certain number of temporary Commissions will be offered at the same time under the same conditions as regards age and qualifications as those required of candidates for permanent Commissions.

All particulars may be obtained by application, in writing or personally, to the Under Secretary of State, The War Office (A.M.D.I.), Whitehall, London, S.W.7.

INDIAN MEDICAL SERVICE

Recruitment of European Officers.

Applications are invited from medical men for permanent commissions in H.M.'s Indian Medical Service. The terms offered include a gratuity of £1,000 on retirement after six years' service, or £2,500 after 12 years' service, together with free return passages for those who no longer desire to remain in the Service. In other respects the terms will be as detailed below.

Candidates must be British subjects under 32 years of age at the time of application, and must be registered under the Medical Acts in force in Great Britain and Northern Ireland.

CAREERS.

The Indian Medical Service offers wide opportunities of medical experience, including clinical, preventive, specialist, and research work. At the beginning of his career an officer is employed on the military side, which has medical charge of the Indian Army. Promotion is on a time scale up to the rank of Lieutenant-Colonel, and by selection to the ranks of Colonel and Major-General. An officer may apply after one year's Indian service to have his name registered for transfer to the civil side, from which appointments are made to Civil Surgeoncies, which are established at the principal civil centres to provide for the medical needs of civil officials and for general medical administrative purposes; to specialist (for example, public health and bacteriological) services; to research posts; and to professorships at the Medical Schools.

NOTE.—It is not possible to state at present what, if any, prospects of employment on the civil side will be open to Indian Medical Service Officers under the proposed new constitution for India.

PAY.

Owing to the state of financial emergency at present prevailing in India the existing monthly rates of pay, which are as follows, are being subjected, under the authority of the Secretary of State in Council, to a temporary reduction not exceeding 10 per cent.

Rank.	Service in Rank.	Basic Pay.	Overseas Pay.	Years of Total Service.
1	2	3	4	5
		Rs.	Rs.	
Lieut.	—	500	150	1st
			150	2nd
Capt.	(i) During first 3 years' service as Captain		150	3rd
		650	150	4th
			£15	5th
	(ii) With more than 3 and less than 6 yrs.' service as Captain		£15	6th
		750	£25	7th
			£25	8th
	(iii) With more than 6 years' service as Captain		£25	9th
		850	£25	10th
			£25	11th
Major	(i) During first 3 years' service as Major		£30	12th
		950		
	(ii) With more than 3 and less than 6 years' service as Major	1100		
	(iii) With more than 6 years' service as Major	1250		
Lieut.-Col.	(i) Until completion of 23 years' total service	1500	£30	13th and over
	(ii) During 24th and 25th years' service	1600		
	(iii) After completion of 25 years' total service	1700		
	(iv) When selected for increased pay	1850		

EXTRAS.—In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the Indian Medical Service. Special high rates of pay are also attached to the numerous administrative appointments open to officers in both branches of the Service.

ANTEDATES IN COMMISSION.

Any service rendered by an officer during the war as a medical or combatant officer, or in a position usually filled by an officer, may be counted as service for increments of pay, promotion retirement and retired pay, but not for gratuity.

One half of any service in the ranks during the war may be counted as service for retirement and retired pay only.

Candidates possessing certain higher medical qualifications may be granted an antedate of one year in their commissions. Past service in certain hospital appointments may also render candidates eligible for an antedate of one year. Persons holding or about to hold resident posts at recognized hospitals may be seconded in those posts for a period not exceeding one year. The maximum period of antedate, secondment, or antedate and secondment combined, admissible under this paragraph, is limited to one year.

OUTFIT ALLOWANCE.

Officers on appointment will receive an allowance of £50 towards the cost of outfit.

PRIVATE PRACTICE.

With the exception of Administrative Officers, military or civil, and officers holding certain special appointments, officers are not debarred from taking private practice, so long as it does not interfere with their proper duties.

LEAVE.

Leave can be taken at reasonable intervals, and adequate rates of leave pay are provided. Extra leave (known as study leave), which may not exceed 12 months in all during an officer's service, may be granted to officers desirous of pursuing special courses of study of a post-graduate nature. During such leave, study allowance, at present fixed at the rate of 12s. a day in the United Kingdom, £1 a day on the Continent of Europe, and £1 10s. a day in the United States of America, is granted to an officer in addition to ordinary rates of leave pay.

PENSIONS.

The rates of pension are as follows:

	Per annum. £
After 17 years' service for pension	400
,, 18 ,, ,, ,, ...	430
,, 19 ,, ,, ,, ...	460
,, 20 ,, ,, ,, ...	500
,, 21 ,, ,, ,, ...	540
,, 22 ,, ,, ,, ...	580
,, 23 ,, ,, ,, ...	620
,, 24 ,, ,, ,, ...	660
,, 25 ,, ,, ,, ...	700
,, 26 ,, ,, ,, ...	750
,, 27 ,, ,, ,, ...	800

These rates are subject to alteration on account of a rise or fall in the cost of living as compared with the year 1919 to an extent not exceeding 20 per cent. in all. With effect from October 1st, 1931, a reduction of 8½ per cent. has been made on this account from the amounts shown.

There are additional pensions ranging from £65 to £350 per annum for officers who have held administrative appointments.

PASSAGES.

An officer on appointment is provided with free passage to India. The wives and families of officers who are married prior to the date of the officers' embarkation on first appointment will also be provided with free passage to India, subject to the payment of messing charges.

Officers and their families are also eligible for passage concessions under which they are granted a certain number of return passages home at Government expense during their service.

INSTRUCTION PRIOR TO EMBARKATION.

Officers are required to undergo courses of instruction at the Royal Army Medical College and at Aldershot, lasting approximately six months, prior to their embarkation for India on first appointment.

Full details regarding these appointments and forms of application may be obtained from the Under-Secretary of State for India, Military Department, India Office, London, S.W.1. The Selection Committee will meet at the India Office early in January next, and the selected candidates will be required to join a course of instruction commencing early in February, 1932, prior to sailing for India in the Autumn of 1932. Applications should be submitted as soon as possible.

APPOINTMENTS—Important Notice.

Medical Practitioners are requested not to apply for any appointment referred to in the following table without having first communicated with the Medical Secretary of the British Medical Association, B.M.A. House, Tavistock Square, W.C.1 (in the case of Scottish appointments, with the Scottish Medical Secretary, 7, Drumsheugh Gardens, Edinburgh).

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)
(FOUNDED 1880.)

Tele. Address: Triform, Wesdo—London.

12, Stratford Place,
Oxford Street, W.1.

Telephone: Mayfair {1782 / 1783

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION have every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUM TENENS.

Assistants and Locum Tenens can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Accounts, etc.

Starch in Infant Feeding

Microphotograph of iodine stained faeces of infant fed on starchy food

Microphotograph of normal faeces of breast fed infant

Starch is never found occurring in any type of milk; the infant's digestive tract is not equipped for the absorption of starch during the first seven months. The addition of starch to the diet of such children makes unjustifiable demands on its alimentary canal, and by disturbing the normal ratio of proteins, carbohydrates, fats and vitamins, prepares the ground for rickets and scurvy. Formerly such addition was recommended on the ground that casein was thereby rendered more digestible. The Roller Process employed in the manufacture of COW & GATE powdered milk modifies the casein and renders it so digestible that the curd is as fine and flocculent as that of breast milk. Moreover, the old-fashioned method of adding starchy products to raw milk carries all the risks inherent in the use of raw milk, with the ever-present danger of tuberculosis and all the other infections carried by raw milk. On the other hand COW & GATE is 200 times cleaner than Certified milk. As an introduction to mixed feeding, at the seventh month, PEPTALAC is strongly recommended. 25% of its starch content is predigested and it has the overwhelming advantage over all other starch preparations employed in infant feeding, usually very low in fats, of a normal fat percentage. It is simply prepared by the addition of water.

Cow & Gate Milkfood

Clinical samples of Cow & Gate and Peptalac will be gladly sent on request to any member of the Medical and Nursing Professions.

FATIGUE

is not a

DISEASE

An exhausted man is not a sick man and general low vitality can not be classified as a pathologic condition.

Patients with low vitality and lack of strength, however, need some treatment to restore their physical and mental depression just as much as a tired athlete needs rest.

The "tonic effect" to the organism and the increased energy-liberating metabolism may be accomplished by the administration of

AN INDEX OF PROGNOSIS
AND END-RESULTS OF TREATMENT

Edited by A. RENDLE SHORT, M.D., B.S., B.Sc.Lond., F.R.C.S.Eng.,
Hon. Surgeon, Bristol Royal Infirmary.
IN CONJUNCTION WITH 27 SPECIAL CONTRIBUTORS.

Sets forth the results, and particularly the end-results, of various methods of treatment, in such a form as will enable the practitioner to obtain a fair, unbiased, reasoned opinion as to the prospects of securing for his patient permanent relief, and the risks of such treatment. It also furnishes data by means of which, apart from the question of treatment, one may arrive at an accurate forecast of what will probably happen to the individual patient.

To-day, when methods of treatment have multiplied, it is more than ever desirable that the doctor, whether he be general practitioner or specialist, should have some such guidance as this, so that he may choose the better and refuse the worse.

"*We have formed a high opinion of the value of the Index of Prognosis . . . and desire to commend the work to our readers as one which they would do well to place upon their bookshelves.*"—BRITISH MEDICAL JOURNAL.

AN ESSENTIAL INCLUSION IN EVERY

MIDWIFERY AND ANAESTHETIC BAG

CO_2 IN RESUSCITATION.

"T B R," in the "British Medical Journal," Nov. 7, 1931, page 878, writes —

"Apropos CO_2 as a respiratory stimulant, at a recent confinement, as the result of premedication of the mother, of instrumental delivery, or of some cause unknown, the child was born in a condition of partial asphyxia. Half an hour's effort to restore respiration proved ineffective, beyond producing a spasmodic inspiratory gasp at intervals. The baby appeared to have definitely decided not to remain. It then occurred to me to try the "Sparklet" apparatus, or, I should rather say, contrivance, which one carries in the anaesthetic bag. The result of discharging a little CO_2 in front of the baby's mouth at the moment of its making a rare inspiratory effort was instant and amazingly effective. The rhythm was started, and in a few minutes all anxiety had vanished. Admittedly there is nothing startlingly new in this phenomenon. I feel, however, that I am justified in relating the experience from the conviction that the average practitioner is unaware that he has to his hand a simple inexpensive little CO_2 container, suggested by a Manchester anaesthetist and manufactured by the "Sparklet" people. I now feel it should have a place in every midwifery bag, and that it will save many an infant life."

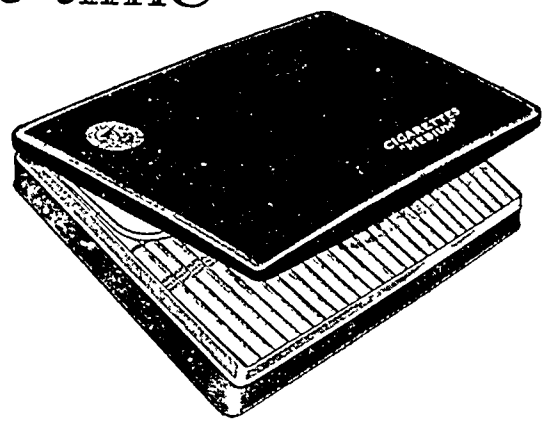
GAS SERVES the modern hospital

To-day the great majority—if not all—of the London Hospitals are large consumers of gas for heating and cooking purposes. Westminster Hospital, for example, has well over 200 gas heating appliances, and the bulk of its cooking for patients and staff is carried out with the aid of gas.

The records of the largest London gas undertaking show that, in their area of supply, no less than 247 hospitals and 586 nursing homes are known to be using gas extensively for heating and other purposes.



How gas serves the modern hospital is described and illustrated in a brochure entitled "Gas in the Modern Hospital," a free copy of which will be sent to anyone who is interested, on application to the address below.

SPECIAL TERMS FOR RECENTLY QUALIFIED PRACTITIONERS.

Everything to look for on a Bottle..

IMITATION may be the sincerest form of flattery, but the extent to which the U.G.B. Medical Bottle is imitated in inferior quality is far from gratifying.

Designed some ten years ago as an ideal dispensing bottle, it is now the standard for this purpose. The consistently high quality, accurate capacity and attractive appearance, places the U.G.B. Medical in a class by itself.

The success of this bottle has been greatly enhanced by the introduction of the "WASHED & STERILIZED READY-TO-USE BOTTLE" packed in non-returnable Dustproof Solid Fibre Cartons—supplied either for Corks or complete with Rustless White Enamelled Screw Caps.

Obtainable from all leading Wholesalers.

INSULIN "A.B."

The world-wide supremacy of Insulin 'A.B.' is due to its unequivocal purity no less than to its well-known potency and stability under all conditions.

Insulin 'A.B.' contains the minute quantity of phenolic preservative originally recommended by the Medical Research Council and still considered necessary by bacteriologists (*Lancet*, Sept. 12, 1931, pp. 582-584) as a complete safeguard against the development of bacteria that may be accidentally introduced during self-administration.

Supplied in three strengths
20, 40 and 80 units per c.c.

Full particulars and the latest literature will be sent free to members of the Medical Profession.

Joint Licencees and Manufacturers:
Allen & Hanburys Ltd.
The British Drug Houses Ltd.

PITUITARY EXTRACT B.D.H.

(Posterior Lobe)

'In considering the whole pituitary controversy the most important question is one of dosage.'
(J.A.M.A., May 3, 1930, p. 1428)

Accurate dosage presupposes a product of unvarying potency and therapeutic effect; hence whether the Pituitary Extract be for use in obstetrics for the prevention of post partum haemorrhage, or in general surgery for the prevention of post-operative shock and collapse, for the relief of post-operative flatulence or other conditions of intestinal stasis, the essential factor is that the extract employed be accurately standardised.

Pituitary Extract B.D.H. is such an extract; it is doubly standardised, being tested for its pressor effect and its oxytocic power.

The Pituitary Extract

that is

Doubly Standardised

STANIFORM

Reg. BRAND. Trade Mark.

METHYL STANNIC IODIDE

OINTMENT
Immediately stops the pain in all cases of burns, scalds, etc.

DUSTING POWDER
For application where a greasy substance is contra-indicated.

LINIMENT
Remarkably effective in treatment of Rheumatoid Arthritis

LOTION
A panacea for Mosquito and other insect bites. Most effective for all purposes where Tr Iodine is employed. Does not stain the skin and there is no sting

TABLETS
Staniform being an organic compound is more easily assimilated than the Tin preparations at present in use

Supplies may be obtained through the Wholesale Druggists, Druggists' Sundriesmen, or Dental Supply Companies

What the Profession says

The following are three recent testimonials received from users reported to the Manufacturers by Medical Men.

"I continue to get every satisfaction from Staniform in the case of carbuncles, boils, whitlows, and, in fact, all kinds of infected wounds."

"In a case of acute eczema on leg, the skin was quite normal with one week after starting applications of 'Staniform.'"

"In a case of an abrasion with large scab the ointment was tried and I was very effective. Scab came away very quickly and healing was very clean and satisfactory."

Similar testimony has been received from a large number of medical men when "Staniform" has been used for the treatment of Burns, Wounds, and Skin Affections

STANIFORM is used in Leading Hospitals.

STANIFORM over a wide field of clinical experience has exhibited positive curative properties. Combining the well known usefulness of Tin in staphylococcic infections with the powerful germicidal properties of Iodine, Staniform is indicated generally in local inflammations, inducing an immediate soothing effect with rapid healing."

STANIFORM LTD., CARNWATH ROAD, LONDON, S.W.6

ACKERMAN-LAURANCE

"Brut-Royal" and "Dry-Royal"

"may be recommended with every confidence. By reason of the very low "content of sugar these wines are "specially suitable for persons with a "rheumatic or gouty tendency."

MONSOL
Liquid GERMICIDE

The use of MONSOL in Obstetric Practice is daily gaining ground and replacing the caustic disinfectants used in the past. The reason being that Monsol has a Selective Action on the Streptococcus Pyogenes, notably the Strain Haemolyticus, and being NON-CAUSTIC can be used at adequate strength to kill these bacteria without the slightest harm to the most delicate tissues. Literature and clinical sample, together with special price list, will be sent to members of the Medical Profession on request.

NON-CAUSTIC

In your next burn case

use this remarkable antiseptic dressing

Keep the dressing wet with full-strength solution

- ANALGESIC — Quickly relieves the pain.
- GERMICIDAL — Prevents infection

Clinical reports from physicians stress the value of Hexylresorcinol Solution S.T. 37 in the treatment of Burns and Scalds.

The technique is simple: cover the affected area with a thin layer of absorbent cotton or gauze saturated with Hexylresorcinol Solution S.T. 37, and bandage lightly to keep it in place. Keep the dressing wet with full-strength solution. In a short time the pain and burning will subside.

Leave the dressing on for 24 hours. Then note how dry, clean and relatively *insensitive* the affected area has become. Continue the use of the wet dressings until healing starts . . . usually two or three days. Then use dry dressings, simply moistening the denuded area with Hexylresorcinol Solution S.T. 37 daily to prevent infection.

SOLUTION S.T.37

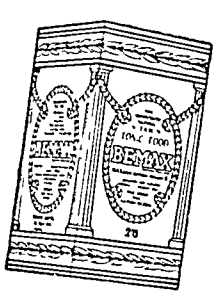
Has the Ordinary Diet Sufficient Vitamin B?

At the request of many correspondents a series of tests were recently conducted at the Bemax laboratories to determine how far the ordinary daily diet is an adequate source of Vitamin B.

The diet chosen for the tests included Eggs, Bacon, Bread, Butter, Beefsteak, Cabbage, Potatoes, Cheese, and a suitable percentage of A and D Vitamin.



The results prove conclusively that such a diet is in fact deficient in B Vitamin and cannot, by itself, meet the nutritional requirements of adults or promote normal growth in children.

Ample evidence is already available to show that partial B Vitamin deficiency results in a progressive deterioration of the digestive system, and may well be the principal cause of the many intestinal complaints which are so common to-day.

Bemax provides an ideal way of supplementing the ordinary diet with an adequate supply of B Vitamin, of which it is the richest known source in B, Bii, and Biii.

Its value as a tonic restorative food can hardly be over-estimated and its use has been attended with striking results in Dyspepsia, Constipation, Sleeplessness, Nervous Debility, Rheumatism, and all B deficiency diseases. As its content of E Vitamin is also exceptionally high it can be used with great advantage in the treatment of Sterility.

Medical Men are invited to write for reports of the tests referred to in this advertisement.

Laboratory Reports on Bemax and Clinical Sample for personal trial will be sent to any Medical Man on request.

Modern diets often lack minerals

To-day, authorities are stressing the importance of the essential mineral salts. In addition to building sturdy bones, and blood rich in hemoglobin, these mineral elements aid metabolism and contribute to nervous stability.

Yet many modern diets cannot be depended upon to furnish the proper quota of minerals, and therefore millions of people suffer from the effects of demineralization. Cooking destroys a variable amount of the mineral value of foods—in some instances as high as 76 per cent.

To correct this loss and to remedy demineralization—with its attendant symptoms of nerve fag, neurasthenia, lowered vitality and loss of energy—a tonic rich in mineral salts is needed.

Compound Syrup of Hypophosphites "Fellows" contains the mineral salts of sodium, calcium, potassium, manganese, iron and phosphorus, together with the added metabolic stimulants—strychnine and quinine. Sixty years of clinical experience the world over testify to its value as a tonic.

Suggested dosage: A teaspoonful in half a glassful of water three or four times daily.

A Distinct Advance Over Preparations of Acetyl-Salicylic Acid

Acetyl-salicylic acid possesses a notable disadvantage. Physicians have proved that it cannot be tolerated by patients suffering with a delicate stomach. Consequently, the value of this medicament in the wide field in which it is indicated is very seriously reduced.

Alasil" completely overcomes this objection. By combining calcium acetyl-salicylate with "Alocol," unfavourable secondary action upon the stomach is prevented. This beneficial influence is undoubtedly due to the presence of "Alocol" (Colloidol Hydroxide of Aluminium), which preparation has brilliantly stood the test of practice in the treatment of hyperacidity and other ill conditions of the gastric tract. "Alasil" is therefore a triumph over acetyl-salicylic acid. It enables higher doses to be administered and maintains the patient's system under its influence for a greater length of time. Analgesic, Antipyretic, and Sedative. "Alasil" is indicated in all cases where acetyl-salicylic acid has been used heretofore.

A supply for clinical trial with full descriptive literature sent free on request.

you can be sure you are prescribing an

"ALL-BRITISH" PRODUCT

*

STANDARDIZATION OF ONE OF THE INGREDIENTS OF THIS FAMOUS BRITISH PRODUCT

A general survey of milk testing done in the laboratory at Slough. Every batch of milk is tested before it leaves the producer, and then re-tested by the Horlick's experts. Three of these tests as shown here are carried out not once but 3 or 4 times after arrival.

*

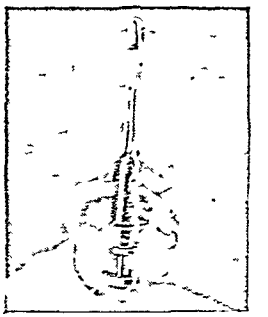
HORLICK'S was originated half a century ago by an Englishman, Sir James Horlick, Bart., and year by year it has won ever-increasing popularity until today it is confidently recommended by the medical profession all over the world.

Just now, when patriotic men and women are uniting their efforts to support home industries, it is particularly satisfactory for doctors and nurses to know that Horlick's Malted Milk is an all-British product.

ENGLISH DAIRY FARMS SUPPLY THE FRESH FULL-CREAM MILK THAT GOES INTO HORLICK'S

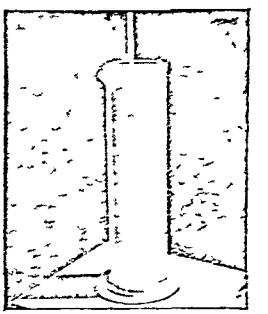
Cows fed on the richest pasture lands of England produce the fresh full-cream milk from which Horlick's is made. Barley from the eastern counties—malted at Horlick's own Maltings in Norfolk, and home-milled British wheat only are used in its manufacture.

BRITISH EMPLOYEES



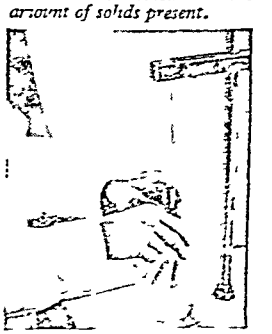
Horlick's Malted Milk Company Ltd., is wholly English in directorate and capital. From factory hand to skilled technician in the laboratories and test rooms—*right through the organization British labour is employed.*

EVEN THE BOTTLES ARE BRITISH!



Only British made material is used in Horlick's factory; even the bottles in which Horlick's is packed and the paper in which it is wrapped are *made in England*

*



HORLICK'S MALTED MILK CO. LTD., SLOUGH, BUCKS

Determining the amount of fat present. The fat content of milk used in Horlick's is well above Government standards

A lactometer floating in a sample of milk. It registers the specific gravity from which can be calculated the amount of solids present.

Testing for acidity. A measured quantity of milk is put into a glass vessel and neutralized with a standard chemical solution. This indicates the freshness of the milk and its suitability for use.

THE ALFRED JEWEL, A PERSONAL ORNAMENT BEARING THE NAME OF ALFRED AND FOUND IN ATHELNEY, WHERE ALFRED THE GREAT TOOK REFUGE IN 878.—Alfred the Great was born in a period of calamity for Teutonic England. The record in the Saxon CHRONICLE for year 851—"came three hundred and fifty ships to the mouth of the Thames, and landed and took Canterbury and London by storm"—is significant. This was not one of the piratical raids from which England had already suffered, but the arrival of an organised army. After years of desperate fighting, Alfred gained an interval of peace for the Kingdom of Wessex. He divided the kingdom into districts and called upon each one to supply warriors and ships for the defence of the country. Thus was started the English navy upon its long period of development, the longest the world has ever known.

The great richness and value of the jewel here reproduced, together with the name of Alfred engraved upon it, afford grounds for believing that it was once King Alfred's property. The front of the jewel contains a figure enamelled upon a plate of gold and protected by a slab of rock crystal, through which the figure can be seen. The back consists of an engraved gold plate. A delicate frame of golden filigree work contains the whole, while around the sides runs the legend: "AELFRED MEC HEHT GEWYRLAN"—"Alfred ordered me to be made."

Date: Alfred born 849, died 901

PORTION OF PAGE FROM THE LAWS OF ALFRED THE GREAT.—Alfred the Great rescued Anglo-Saxon civilisation and was a pioneer in legislature, literature and art. He had a European education, and his outlook was broadened by the traditions and culture of the Carolingian court: in fact, he played in England much the same part as Charlemagne did on the Continent. He founded schools and imported scholars, amongst whom were Grimbald, brought from France, John of Old Saxony, and Asser from South Wales. He translated from Latin into Anglo-Saxon the PASTORAL of Pope Gregory, the treatise DE CONSOLATIONE PHILOSOPHÆ of Bœthius, the ancient history of Orosius and Bede's history. Alfred repaired and restored the monasteries and their schools, and founded others at Athelney and Winchester, keeping ever before his mind the setback which England had endured at the hands of the Danes.

The John B. Murphy Oration

[ABRIDGED]

ON

MURPHY, AND SOME PRINCIPLES OF URINARY SURGERY*

BY

A. H. BURGESS, M.Sc., F.R.C.S., LL.D.

PROFESSOR OF CLINICAL SURGERY, VICTORIA UNIVERSITY OF MANCHESTER

We are met to commemorate a great surgeon and a great man, one who was recognized throughout the civilized world as the greatest American surgeon of his time, and one whom future generations will undoubtedly place among the greatest surgeons of all time. It seems only fitting therefore, that at the commencement of each annual clinical congress of the American College of Surgeons, in the foundation of which he took so keen an interest and played so active a part, we should recall in respectful and appreciative remembrance John Benjamin Murphy.

It was my good fortune to meet Murphy on three occasions, the last immediately before the outbreak of the war, when this congress met in London, under his presidency. Well do I recall his commanding presence, his handsome appearance, his tall and erect bearing. Any slight surprise on first hearing him speak, that nature had not endowed him also with a proportionately powerful voice, became rapidly dissipated in the beauty, the grandeur, and the consistence of the argument, and the obvious sincerity, enthusiasm, and earnestness of the speaker. Murphy undoubtedly possessed, in a superlative degree, the power of presenting facts and deductions from them in so orderly, concise, and forceful a manner as to convey the profoundest conviction. None who heard could for a moment doubt but that he himself was firmly convinced of the truth of all his statements, and that such belief was not born merely of intuition, but was founded upon prolonged observation of his facts and their careful testing by direct experiment.

It is of necessity, however, by his published writings that posterity will judge him, nor need its verdict be feared. The volumes of his *Surgical Clinics*, published bi-monthly from 1912 until his death, reveal his innermost thoughts on the most varied topics of surgical interest, and many truths are there presented in the form of aphorisms so peculiarly appropriate as to command remembrance. Besides articles in textbooks and yearbooks of general surgery Murphy published sixty-six papers in medical and surgical journals, all of them substantial additions to surgical knowledge, and many of epoch-making importance, practically everything he originated has become standard practice to-day.

In this era of increasing specialism, it seems almost incredible that, within such recent times, any single individual could have written with such intense originality and authority upon so many and such diverse branches of the surgical art. As W. J. Mayo so aptly phrases it of Murphy—"We must remember the number of targets at which he shot, and that he always rang the bell." Murphy's earlier writings were concerned mainly with abdominal surgery, and it was undoubtedly in connexion with his "button" for intestinal anastomosis that he first became prominently known outside America. Introduced only after many careful experiments upon dogs, it provided surgeons with an easier, quicker, and safer method of anastomosis than any hitherto available. Its supreme value, however, has been as an educational factor—it taught us the essential principles of union between peritoneal-clad surfaces. Though it is now the almost universal practice to dispense with any form of mechanical device in performing visceral anastomosis, yet it can be truly said that the Murphy button has been the most valuable single educative step in the history of abdominal surgery, and that without it the marvellous progress since achieved would not have been possible.

The closely allied conditions of appendicitis and peritonitis soon attracted Murphy's attention, and I cannot conceive that the essential features in their treatment could be stated more concisely or more accurately than in Murphy's masterly paper on perforative peritonitis. Though his words were written almost a quarter of a century ago, they still represent the truth, the whole truth, and nothing but the truth, in the treatment of acute peritoneal infections, a truth, moreover, which amounts to an almost complete reversal of what was previously considered orthodox. Of all Murphy's contributions to surgical progress, this recognition of the defensive and protective capabilities of the peritoneum, and the principles by which these can be aided and not hampered in their beneficent efforts, constitutes, in my opinion, his supreme achievement. Only those of us who, by length of experience, are able to contrast the results of surgery in peritonitis prior to Murphy's epochal work with those now obtained can realize what an enormous number of lives he has already been the means of saving, and what an immeasurable load of human suffering he has already prevented.

To a remarkable extent Murphy possessed the ability to sift rapidly the essential from the non-essential, and to establish broad basic principles. My predecessors in this Oration have shown how he applied these principles in certain selected spheres of his surgical activity, but only scant reference has yet been made to that of the urinary system. I propose, therefore, to consider some of the principles of urinary surgery, and Murphy's work in relation thereto.

RENAL FUNCTIONAL TESTS

One of the first of these principles, and one which Murphy continually stressed throughout his teaching, is that the state of the renal function as a whole must be thoroughly appreciated before any capital operation is performed upon the kidney or, indeed, upon any part of the urinary tract. It is essential to know beforehand, not only that there is a second kidney actually present, but also that its functional capacity is sufficiently good to carry on life should its fellow require removal. In pre-cystoscopic days it was often quite impossible to obtain this information, and disaster was not infrequent. My old chief and predecessor in the chair of surgery once confessed to me that during his thirty-five years of practice he had on three occasions removed a patient's only working kidney. Such errors, though at that time unavoidable, are quite inexcusable since the advent of the cystoscope and of the many tests of renal function. These have enabled us to measure the functional capacity of the kidneys with an accuracy that is truly remarkable, and which compares very favourably with that obtainable in any other system of the human body.

Of the many tests of renal function that have from time to time been proposed, the surgeon is concerned chiefly with those that, while trustworthy, are yet readily practicable. Of the blood tests, the estimation of the urea-nitrogen, and of the kidney elimination tests, the "urea concentration" test of MacLean, the indigo-carmine, and the phenolsulphonephthalein tests are those most in favour in England. The last is certainly the best quantitative test, but the indigo-carmine has an exceedingly high qualitative value, and is particularly useful for detecting differences in function between the two kidneys.

* The full text will be published in *Surgery, Gynecology, and Obstetrics*, the official organ of the American College of Surgeons.

Reliance should never be placed, however, on any single test, and in my wards the blood-urea, urea-concentration, and indigo-carmine tests are used as a routine in all cases.

Though the older method of pyelography, by the introduction of opaque media directly into the renal pelvis through the ureter catheter, yields valuable information of its anatomical shape, size, and situation, yet it gives no evidence of the renal function. Many workers, chiefly in America and Germany, have recently attempted to remedy this defect by introducing a shadow-casting substance into the blood stream, so that, upon excretion in the urine, radiography would reveal the outlines of the pelves and ureters. Sodium iodide in 10 per cent. solution, at first alone and later in combination with urea, uroselectan, abrodil, and uroselectan B, have been tried successively for this purpose. Researches are in progress with compounds of bromine, which are said to be safer and less costly than those of iodine, and, as there is little doubt but that in the near future preparations will be discovered still less toxic and yielding a deeper shadow, this "intravenous" or "excretion" pyelography promises to be of the greatest value to urology; it may, indeed, prove epoch-making. It has the advantage over the older or "retrograde" pyelography that it does not require ureteral catheterization, and can therefore be used where this is difficult or impossible. Moreover, it gives bilateral pyelograms, and avoids the risk, inherent in the "retrograde" method, of conveying infection in septic and tuberculous cases. It must not, however, be regarded as a substitute for, but rather as complementary to, retrograde pyelography, and where the renal function is so defective that the drug is not excreted in sufficient quantity to cast a recognizable shadow, the latter will still be required.

Renal Back Pressure

Another principle to which Murphy constantly referred, and one, moreover, applicable to systems of the body other than the urinary, is that long-standing pressure upon an organ or system should never be released suddenly, but always gradually. The evil effects of pressure are well known, and if this be brought to bear suddenly upon an organ it may lead to its actual rupture, or, short of that, to damage more or less irreparable. If, however, increasing pressure be applied slowly, so great is the adaptability of the human tissues to altered circumstances that compensatory mechanisms arise which delay its injurious effects. If sudden relief be given, there may follow such a repercussion as even to exceed in its harmful effects the original pressure, whereas gradual alleviation may lead to recovery, the completeness of which will vary inversely with the delay in its application. It can, in fact, be laid down as a general principle that the greater the pressure the more gradual should be its relief.

The best illustration of this is undoubtedly afforded in the treatment of "back pressure" upon the kidneys, such as occurs with a progressively increasing obstruction from the prostate gland. Once the prostate gland commences to impede the urinary stream, from that moment onwards the whole of the urinary tract proximal to the prostate inevitably suffers from the steadily increasing pressure. Since, however, Nature has granted us a fairly generous reserve of renal tissue over and above our actual necessities, clinical manifestations of such pressure may not be apparent until comparatively late. We then meet with the symptoms typical of chronic uraemia, and if the back pressure continues unrelieved, gradually increasing coma supervenes and heralds death.

These back-pressure effects are seen in their most extreme form in those cases of "silent" distension of the bladder, which are not infrequently associated with a small contracted fibrous prostate, or with a small "middle lobe" enlargement. Such a patient walks into your consulting room feeling perfectly well and often looking so, complaining only that he "makes too much water," which is the layman's mode of expressing frequent micturition. The bladder is found distended to the level of the umbilicus or beyond, yet without arousing in him the slightest sensation of distension; his urine, which is passed frequently and in very small quantities, is merely the "overflow" from the hugely distended bladder; it is clear, very pale, with a urea content of 0.5 per cent. or less, while his blood urea may be from 100 to 300 mg. per 100 c.cm. of blood, or even higher. He scoffs at the idea that there is anything seriously wrong with him, and yet, notwithstanding, he is on the very brink of uraemia. The immediate cause of his dangerous state is not the actual pathological condition of his prostate gland, but the back-pressure effects it has produced upon his kidneys; hence our first concern is the release of the kidneys from such back pressure rather than the removal of the prostate—that is for future consideration.

This opens up the interesting question as to what should be our main reason, as surgeons, for ever recommending a patient to undergo the operation of prostatectomy, especially if he be only in the early stages of his trouble. The patient's mind is concentrated upon the purely local effects—the difficulty and frequency of micturition—and it is the removal of what he regards rather as nuisances that reconciles him to the radical operation. The surgeon, however, advises prostatectomy for a much stronger reason—namely, as a measure designed primarily to prevent progressive destruction of the kidneys from back pressure. It cannot be too strongly emphasized that a patient with even a slight degree of prostatic obstruction cannot possibly have perfectly healthy kidneys; from the first moment of obstruction the kidneys commence to suffer; prostatic obstruction and healthy kidneys are as incompatible as are heat and cold.

If this renal back pressure be released suddenly, as by completely emptying a chronically distended bladder at one catheterization, then a characteristic sequence of events is frequently observed. The urine next passed spontaneously, or withdrawn by catheter, contains blood, the haemorrhage being of renal rather than of vesical origin. This haematuria may last for two or three days only, or it may continue to the end. The urine steadily diminishes in quantity and deteriorates in quality, the patient becomes increasingly drowsy, and all the signs of uraemia appear within about fourteen days of the first catheterization, coma and death supervening shortly afterwards. It is because of this comparatively long interval of from twelve to fifteen days between the first catheterization and the fatal issue that many practitioners fail to recognize the real causal relationship of the one to the other. I well remember an enthusiastic house-surgeon who, when I entered my wards one morning, proudly greeted me with the information that he had just withdrawn eighty ounces of urine from a case of prostatic obstruction; I recall, also, how his countenance changed from one of pleasure to one of pained and surprised incredulity when I gently hinted that he had possibly also withdrawn the man's last chance of recovery; and I was unfortunately, this proved so, since death from uraemia occurred on the fourteenth day. The risk of catheterization in chronic prostatic obstruction cannot be too strongly emphasized; it constitutes a risk considerably greater than that of many major abdominal operations and one that should never be undertaken save under appropriate physical and aseptic conditions. The plea of urgency cannot here be pleaded, as it might properly be in a case of acute prostatic obstruction, since in chronic obstruction the patient is not in any distress, and is

indeed, usually quite unaware of the distended state of his bladder.

The various methods of effecting gradual renal decompression need not be referred to in detail; the more gradually and continuously they act the greater their safety. In the most serious instances, however, and especially in those of that "silent" distension of the bladder to which I have already referred, and where instrumentation even of the slightest kind is fraught with danger, decompression should commence with medical rather than with surgical measures—rest in bed, warmth, vapour baths, milk diet, restriction of fluids, diaphoretics, and saline purges. When by these means the fundus of the bladder has been induced gradually to recede below the umbilicus, decompression may be continued with an indwelling catheter connected to the Shaw-Young or other controlling apparatus.

HAEMATURIA

Another important principle in urinary surgery is that haematuria should never be regarded lightly. While haemorrhage from other sources may not necessarily be of serious import—for example, epistaxis, bleeding from haemorrhoids—haematuria is always of weighty significance. Fortunately for the diagnosis of its cause, haematuria is usually accompanied by other symptoms of urinary disorder, which assist in its interpretation. A very interesting group is constituted by those cases where haematuria is absolutely the only symptom of which the patient complains; indeed, many of them volunteer the statement that, had they been blind, and so unable to detect the altered colour of their urine, they would never have known there was anything wrong.

Haematuria of this symptomless type may arise from diverse pathological conditions; in fact, almost any disease of the urinary tract may occasionally so first declare itself, though with most of them this is very exceptional. In 1927, I analysed 200 cases that had come under my own observation, and found that the haemorrhage was of vesical origin in 60 per cent., and of renal origin in 40 per cent. Of the whole series, 50 per cent. were due to benign and 31 per cent. to malignant neoplasm. Of the renal haematurias, 45 per cent. were from malignant neoplasm, while of the vesical haematurias, only 25 per cent. were associated with malignancy.

The term "essential" or "idiopathic" haematuria is sometimes used to indicate renal bleeding of unknown causation, but such a title merely cloaks our ignorance, and is one against which every scientific mind must revolt. Murphy was himself very sceptical of the reality of idiopathic haematuria, and stated that, in his experience, blood in the urine always indicated pathology in the genito-urinary tract. Yet in one of his clinical lectures he referred to a case in which Senator of Berlin had removed a kidney for extreme anaemia from haematuria, and which, on subsequent microscopical examination, failed to reveal any cause for the haemorrhage. The disquieting truth remains, therefore, that a kidney may take upon itself to bleed, and to bleed so furiously as to threaten death from haemorrhage and necessitate nephrectomy for its arrest, and yet subsequent careful macroscopical and microscopical examination by a skilled pathologist may fail to disclose any abnormality whatsoever. I have met with three such cases.

In symptomless haematuria it is only by cystoscopy that the source of the haemorrhage can be determined with certainty, and this should be regarded as a matter of extreme urgency, particularly if bleeding is actually occurring. Murphy constantly insisted upon this point, and yet it still happens much too often that the practitioner's first efforts are directed, not to ascertaining the source of the bleeding, but to its arrest; he puts his patient to bed and administers morphine and internal styptics. Although this course may allay the alarm which many patients not unnaturally feel at the discovery of blood in their urine, yet it may, in the long run, prove the greatest possible disservice; it is much more advisable to allow the haemorrhage to continue until arrangements can be made for a cystoscopic examination. Cystoscopy is here as urgently called for as is early laparotomy in acute abdominal crises, and if it be postponed until haemorrhage has ceased it will often fail, in renal haematuria, to indicate its source.

When, through the cystoscope, blood has been observed to escape from one ureteric orifice only, a thorough investigation must be instituted by all the urological methods to ascertain the pathological lesion in the corresponding kidney. By them positive evidence may be obtained of certain conditions—for example, calculus, neoplasm, or tuberculosis—but when their findings are entirely negative the interesting question arises whether we are to treat the bleeding expectantly, or whether we should explore the kidney operatively. Those who advocate surgical exploration do so mainly because of the fear that otherwise an early malignant neoplasm might be overlooked. Most American writers favour expectancy, but my own inclination is towards exploratory nephrotomy in these circumstances, and only when this has been undertaken with a negative result do I care to label the haemorrhage as "idiopathic" or "essential." It was by such exploratory nephrotomy that the two earliest malignant renal neoplasms I have ever operated upon were discovered, and both these patients are alive and well eight years and four years respectively after nephrectomy. Should exploratory nephrotomy fail to reveal any macroscopic lesion, a small slice of the parenchyma is removed for microscopical examination, and the kidney carefully sutured. The case is now regarded as one of "idiopathic" haematuria, and should the haemorrhage ever recur it may then be treated expectantly with the confidence that a malignant growth has not been overlooked.

EARLY SYMPTOMS: RENAL TUBERCULOSIS

One of the most characteristic features of Murphy's clinical teaching was the extreme importance he so consistently attached to an accurate account of the early history of the complaint under consideration, and especially to the order of onset of the respective symptoms and signs. Acute appendicitis affords the best example, and Murphy's description of the order of onset of the symptoms of this disease will long remain classic. In the differentiation of renal conditions, Murphy was equally insistent upon the value of the onset symptoms—in renal calculus it is pain that is to be expected, in neoplasm of the kidney it is haematuria, while in renal tuberculosis it is increased frequency of micturition.

The subject of renal tuberculosis had a profound personal interest for Murphy, for in 1883, while a post-graduate student in Vienna, he had a sharp attack of haematuria, which a Viennese professor ascribed to tuberculosis of the right kidney. The haematuria soon ceased and never recurred, nor is there any record of the tubercle bacillus ever having been found, though throughout his life he had slight transitory albuminuria after great exertion or following any special mental strain. At the necropsy upon Murphy, which he himself had requested to be made, his right kidney was found to be extremely small, with extensive cicatricial change; no giant cells were discovered microscopically, and the opinion formed was that the condition represented a chronic persistent infection due, probably, to some organism other than the tubercle bacillus. The cause of death was angina pectoris from atheroma of the coronary arteries, and this was regarded as an infection metastasis from the right kidney. His friend, Dr. W. A. Evans, has expressed the

opinion that, had the right kidney been removed in 1883, or at any time within twenty years after, this arteritis would have been prevented.

The evolution of our knowledge of urinary tuberculosis, particularly the great progress that has been made in its earlier recognition, constitutes one of the most interesting and beneficent advances in neurology that have occurred within our time. Our present-day ability to recognize the existence, and often also the extent, of tuberculous change in a kidney from the cystoscopic appearance of the corresponding ureteric orifice—and this we owe largely to the work of my fellow countryman E. Hurry Fenwick—always appeals to me as the most fascinating of the cystoscope's innumerable and priceless contributions to urology.

Murphy considered renal tuberculosis to be usually a blood-borne infection, the bacilli entering the blood, by way of the lymph stream, from a primary focus in the bronchial glands. He believed (1) that in visceral tuberculosis tubercle bacilli may be found in the urine even in the absence of a tuberculous focus in the kidney, (2) that in the great majority of early cases the disease was unilateral, and (3) that early cases could be cured by non-operative measures, prominent among which he placed the injection of tuberculin. In the fifteen years that have elapsed since Murphy's death, although considerable discussion has ranged around these same three questions, and much clinical and experimental investigation has been carried out, no general agreement has yet been reached. Many recent workers now hold (1) that "secretory bacilluria" does not exist, and that the presence of the tubercle bacillus in the urine from a kidney denotes the actual existence therein of a focus of tuberculosis, even if microscopical only; (2) that renal tuberculosis is at first a bilateral condition; and (3) that the initial renal lesions frequently heal.

Despite these divergent opinions, the surgical position of to-day does not differ materially from that of Murphy's time. Renal tuberculosis, if clinically unilateral, should be treated by nephrectomy, whereas, in clinically bilateral involvement, nephrectomy should be performed only very exceptionally, as when there is severe pain, haemorrhage, or acute sepsis in a tuberculous kidney, whose fellow is but slightly affected.

In tuberculosis of the epididymis, Murphy was a forceful advocate of the conservative operation of epididymectomy as opposed to castration. He wrote: "There is no more occasion for taking out the testis proper in the early stages of tuberculous epididymitis than there would be for taking off the caput coli if you had a case of appendicitis." The treatment Murphy recommended was the removal of the epididymis, and as much of the vas as could be reached from the groin; he never excised a seminal vesicle, and shortly before his death stated that he had never seen a case presenting clinical evidences of tuberculous involvement of a seminal vesical that did not entirely heal after epididymectomy, without further operation. These views, as is well known, are strongly opposed by H. H. Young, who, however, is at one with Murphy in protesting emphatically against the unnecessary removal of the testis, which hitherto has been so frequently practised.

PROSTATECTOMY

In his earlier work in radical prostatic surgery Murphy removed this gland by the perineal route, and in 1904 recorded fifty-one perineal prostatectomies with one death. From this time onward, however, he regarded the suprapubic route with steadily increasing favour, and shortly before his death stated that he removed all his enlarged prostates suprapubically. This gradual change of attitude towards perineal prostatectomy is typical of the majority of surgeons whose work has covered approximately the same period, and the oft-debated question as to the relative merits of perineal and suprapubic prostatectomy would appear to have been decided, for the present at any rate, in favour of the suprapubic. Nevertheless, we have in this country the world's greatest perineal prostatectomist in the person of Dr. H. H. Young—the archprotagonist of the operation itself. At the hands of the average surgeon, however, and not of a super-surgeon, perineal prostatectomy carries with it the two dangers of wound of the rectum and of defective sphincteric control, and these, combined with the greater ease of performance of the suprapubic operation, account for the present-day preference for the latter.

In recent years, the death rate of prostatectomy from its former two chief component factors—renal insufficiency and haemorrhage—has been greatly lessened, and it is infection that now constitutes its most serious risk.

One form of this infection of especial interest is post-operative epididymitis, the frequency of which has been varyingly stated as being from 20 to 39 per cent. Since in the vast majority of the cases the infection is conveyed along the vas deferens, division of the vas can be relied upon to prevent epididymitis provided it be performed before the organisms have reached the epididymis. Murphy recognized this, and wherever the history disclosed a former epididymitis, however mild, he always divided the vas bilaterally immediately prior to removing the prostate; he does not appear, however, to have adopted it as a routine procedure. Since 1922 I have divided and ligatured the vas on both sides in all my prostatectomies, and I have not met with a single case of epididymitis in 177 consecutive operations. There can be no objection to vaso-ligation from the point of view of future sterility, since, in any event, the patient after prostatectomy will almost certainly be sterile, though far from necessarily impotent. Indeed, if there be any truth in Steinach's contention that vaso-ligation leads to "rejuvenescence," then the patient gains this additional benefit.

CONCLUSION

The time allotted to me will not permit of reference to the many other interesting features of Murphy's work in urology, but I trust that enough has been said to indicate that, as in other fields to which your previous Orators have drawn attention, so in this field of urinary surgery Murphy held a foremost place, and was, in many respects, a pioneer.

SHOCK FOLLOWING BLOOD EXTRAVASATION

WITH SPECIAL REFERENCE TO THE TREATMENT OF ACCIDENTAL HAEMORRHAGE*

BY

O'DONEL BROWNE, F.R.C.P.I., M.C.O.G.

LATE ASSISTANT MASTER, ROTUNDA HOSPITAL, DUBLIN; ASSISTANT GYNAECOLOGIST, SIR PATRICK DUN'S HOSPITAL, DUBLIN

In April, 1931, at the eighth International Congress of Obstetrics and Gynaecology in Glasgow, I brought forward twenty-eight cases of albuminuria which were observed to appear as a result of absorption from recent localized blood extravasations.

In all the material considered some degree of shock was present, and it was evident that the severity of the shock which could be induced by reabsorption from a blood effusion depended on the facility of reabsorption rather than on the quantity of blood which was extravasated. As an example of this, there was one case in which the total quantity of blood extravasated

* Paper read in the Section of Obstetrics and Gynaecology at the Annual Meeting of the British Medical Association, July, 1931.

approximately three-quarters of a pint. There was no previous loss in this case, and before the blood effusion the blood pressure was 126 mm. Hg. One and a half hours after the rupture of a tubal pregnancy and extravasation of the three-quarters of a pint of blood the blood pressure had fallen to 68 mm. Hg. There was a fast feeble pulse, subnormal temperature, pallor, sweating and restlessness. From the time of removal of this small extravasation the blood pressure rose steadily, and in six hours had reached 100 mm. Hg.

Still more interesting was the marked shock and blood-pressure collapse which followed the formation of a small effusion in the perineum, due to the tearing of a blood vessel at the time of delivery. In this woman the blood pressure fell from 115 to 90 mm. Hg in the course of half an hour. Symptoms and signs of shock were well marked, and the removal of about 2 oz. of effused blood immediately restored the blood pressure and the general condition.

Other instances have been noted in which a similar sequence of events followed blood effusion, and made it evident not only that severe shock was induced by reabsorption from blood effusions of small size, but that the clinical condition could be accurately estimated by blood-pressure readings.

The points which I wish to bring before you to-day are the intimate relationship between certain blood extravasations and the subsequent urinary and blood-pressure disturbances, and the fact that these, taken in conjunction with clinical phenomena, constitute obstetric shock. I wish also to illustrate the effects of, and to attempt to impress the necessary indications for, the various means of active treatment of shock.

TECHNIQUE OF OBSERVATIONS

The following points were investigated from the time the patient first came under observation: two-hourly records of systolic blood pressure, pulse rate, and temperature; estimation of the volume of urine and its albumin content (specimens were taken four-hourly as a routine, in some instances two-hourly by catheterization); full notes on the clinical condition and the effects of treatment on blood pressure and urinary phenomena.

From the material under consideration it appears very definitely that shock is produced by reabsorption from altered blood effusion, and that the first symptom in the onset of shock is a fall in blood pressure. Almost simultaneously with the fall in blood pressure the pulse rate becomes slower, the diminution in its volume not being appreciable save with the aid of a sphygmomanometer. This initial fall in blood pressure may be approximately 10 to 15 mm. Hg, but varies in individual cases.

Coincident with the further fall in blood pressure there is an increase in the pulse rate to between 100 and 120, with further loss of its volume. Sweating, pallor, flaccidity of muscles, with restlessness, coldness, vomiting, and a sense of faintness, overcome the patient. This change may be expected when the blood pressure reaches the 100 mm. Hg level, and the symptoms become more urgent as the blood pressure falls.

In the event of the blood pressure remaining at a low level, or falling still further, the anoxaemia and sluggish renal circulation become more marked. Figures in such examples show diminution in the urinary output with increasing albumin content. From the foregoing remarks, it is evident that should this fall in blood pressure continue, finally there would be no urinary secretion, and the last few drops found per catheter would boil solid. Such has been the case in several recorded instances, and the opposite phenomena are noted when recovery of the blood pressure takes place.

In women in whom the blood pressure reached 40 to 60 mm. Hg, shock was very marked, but in one case recovery occurred even after no reading could be obtained. From this it may be pointed out that recovery can be hoped for, with appropriate treatment, even in the most severe degrees of shock. In the fatal cases which were recorded the blood pressure showed a persistent downward course, and the cause of the shock was found only at post-mortem examination in the form of retroperitoneal and subserous effusions whose volume varied from 2 to 8 oz. If these extravasations had been removed at a safe stage of shock, the patients would almost certainly have recovered.

Professor Tweedy first described the condition which he named "haemorrhagic shock" in 1918. He stated that this was probably due to reabsorption of some toxic product evolved from clotting blood being in contact with fresh blood. This state of affairs would allow very free reabsorption, as it infers that the vessels are still open and capable of reabsorbing any toxic products. He also maintained that relaxation of all smooth muscle was a constant feature of severe shock.

This has been very fully verified in the numerous examples of blood-pressure collapse which I am able to place on record in connexion with blood reabsorption subsequent to extravasation. We may therefore take it as an established fact that the most definite information as to the exact condition of the patient and the state of her smooth muscles is to be determined by blood-pressure observation.

EFFECTS OF VARIOUS TREATMENTS ON SHOCK

I wish now to consider the effects of various treatments on the condition of shock. The routine pre-operative treatment in all the instances which I noted while in the Rotunda Hospital may be summarized as follows:

1. Warmth and elevation of the end of the bed.
2. Hot drinks, rectal coffee salines with brandy.
3. Submammary and intravenous salines.
4. Hypodermically; ether, brandy, camphor in oil, pituitrin, ephedrine, and morphine.

In reviewing these procedures it should be remembered that they are used in conjunction with each other, and their effects are best judged by the response which is obtained in blood-pressure elevation. The most important elements in this treatment appeared to be warmth, fluids, morphine, pituitrin, and ephedrine. The last produces an elevation of 15 to 20 mm. Hg, and its effect is sustained for at least half an hour. In this respect it is far more potent than pitpressin, pituitrin, or adrenaline.

Of even greater importance than the prevention of increased extravasation are the removal of already extravasated blood and the prevention of its reabsorption. All these principles are well illustrated by the methods adopted in the Rotunda Hospital for the treatment of accidental haemorrhage. Here it must be emphasized that the cases included are only those which would have produced severe constitutional symptoms had they not been subjected to immediate prophylactic treatment.

On the appearance of the initial symptoms restorative treatment is adopted to combat the shock. This may vary from merely applying warmth to the more energetic routine, such as morphine, ephedrine, salines, etc. The value of submammary salines in this connexion cannot be overestimated. The salines administered are either sodium bicarbonate or sodium chloride, in the strength of 1 drachm to the pint; glucose 5 to 10 per cent. may be added in saline.

The infusion is given with a tube and funnel, to which are attached two large infusion needles. When the saline is flowing, these needles are plunged into the connective

tissue between the gland and the pectoral muscles parallel to the chest wall, the funnel being held 1 to 2 feet above the patient's head. The correct surface marking is known by the fold between the uplifted breast and the chest wall. Full aseptic precautions are very necessary, and it is also most important to administer the right amount of saline at the correct temperature. It should be poured into the funnel at 115° F. so that it will reach the body at 100°. Too co'd infusion adds to shock, and sloughing of the breast has followed too hot salines, or excessive quantity. A fair average is one pint under each breast, and this may be repeated every two to four hours, if necessary.

This combined prophylactic treatment will deal with the shock and produce a rise of 10 to 15 mm. Hg. It is therefore of great value, but will not in itself prevent blood flow or reabsorption. In a number of cases labour follows the partial restoration of the patient, and accidental haemorrhage, accompanied by labour, is rarely a serious condition. Even though the labour has started, rupture of the membranes should not be neglected, as it will expedite labour and prevent blood flow with further reabsorption by causing contraction and retraction with c'osure of the open sinuses. In the event of labour not starting in spite of the restorative methods for raising the blood pressure, the membranes must be punctured, a tight binder applied, and 1/4 c.cm. of pituitrin given at half-hourly intervals until 1 c.cm. is administered. This will cause partial emptying of the uterus, with consequent retraction of the muscle fibres and partial or complete closure of the sinuses.

In the more serious type of cases in which symptoms grow progressively worse in spite of the already mentioned treatment, other procedures must be adopted. Here the blood pressure is in the neighbourhood of 80 mm. Hg; pallor, restlessness, faintness, and sweating are more marked. In these cases there is a continuance of the outflow of blood and its reabsorption. In these circumstances, Sir William Smyly strongly advocated plugging of the vagina by the use of numerous pledgets of cotton-wool squeezed out of lysol solution. He asserted that by this means labour pains were promoted and the os opened. In the same connexion Tweedy claimed that the plugs exerted direct pressure on the uterine vessels.

In later years this treatment has not been so enthusiastically advocated, for the reason that it undoubtedly increases shock. Its supporters, while admitting this to be true, maintain that it hinders, if not altogether stops, the fresh outflow of blood. It is probable that the prejudice against plugging has arisen from the fact that it has been employed in cases where the blood pressure has been in the neighbourhood of 60 to 80 mm. Hg; the additional shock due to this operation has reduced it to a still lower and more dangerous level. In addition, plugging does not remove the cause of the shock, but only prevents further loss taking place. In such low degrees of blood pressure, plugging the vagina should not be considered, as rapid emptying of the uterus by Caesarean section offers the best chances of success.

In the past, much misgiving has arisen in connexion with Caesarean section, for it was considered that in the presence of an atonic uterus the dangers of post-partum haemorrhage would be great. In practice this is not so, as the muscle, though flabby, will rapidly retract on emptying the uterus, with control of the bleeding. This has been the universal experience in the Rotunda Hospital, where the operation was first performed for this condition, and is still adopted with success by the present Master, Dr. Bethel Solomons. There is no doubt as to the claims which have been made on its behalf, and when performed rapidly under ether or gas-oxygen the ensuing shock is small and the recovery rapid.

On the other hand, the statistical report on the operation of Caesarean hysterectomy is very high, probably 50 per cent., under similar conditions. It must therefore be rightly considered an unjustifiable operation.

It must never be forgotten that very severe haemorrhage can occur from rupture of a blood vessel other than in the uterine wall, and extravasations occur into the abdominal cavity as well as into the broad ligaments. This complication can only be dealt with by abdominal section.

It has already been pointed out that it was not in accidental haemorrhage alone that shock was found to develop subsequent to blood extravasations. In such conditions as haematoma of the vulva, ruptured tubal pregnancy, my experience was that shock occurred in a similar manner, and that the degree of shock appeared to depend on the facility of reabsorption rather than on the quantity of blood extravasated.

It must not for one moment be concluded that every case of blood effusion will cause shock; it is only a certain percentage which will develop these phenomena. It is best seen when oozing takes place over a clot, as in this instance the clot mechanically keeps the vessels open and readily allows reabsorption to take place.

CASES ILLUSTRATING SHOCK SUBSEQUENT TO BLOOD EFFUSION

M. C. (1) was first seen with uterine bleeding and blood pressure of 116 mm. Hg at 5 p.m. The bleeding was of no consequence, but, nevertheless, at 7 p.m. she was in marked shock with pallor, sweating, pulse 120, and a blood pressure of 63 mm. Hg. The uterus had been the size of an average six weeks' pregnancy, but was now ballooned out by the detached ovum and about 4 to 6 oz. of blood clot. The uterine contents were emptied, and a hot intrauterine douche given. The blood pressure and urinary output recovered almost immediately, and within two hours the patient could be clinically considered normal.

M. R. suffered from concealed accidental haemorrhage. In spite of all prophylactic treatment, puncture of membranes etc., the shock persisted, and it was thought the patient would die with any manipulation. When the blood pressure was at 85 mm. Hg, the pulse was almost imperceptible at 120; pallor, faintness, coldness, sweating, and anxiety were very marked. The condition was too critical to temporize by plugging the vagina, and death would have followed any further conservative treatment. As a desperate resort classical Caesarean section was performed with rapid removal of the foetus, placenta, and about three-quarters of a pint of blood clot. The uterus retracted perfectly, though pains were absent, and the blood pressure rose rapidly from the time of emptying the uterus.

In contrast to the cases mentioned, in one of which recovery followed from an apparently hopeless condition, I would like to quote the example

M. C. (2). The blood pressure readings in this case of concealed toxaemic haemorrhage are particularly interesting. At the onset the prophylactic treatment caused an increase in blood pressure from 136 to 152 mm. Hg. Shock was present in moderate degree, and delivery took place spontaneously at this level. There was no post-partum haemorrhage, but in spite of all prophylactic treatment there was a persistent fall in blood pressure. Shock increased, the blood pressure fell to 48 mm. Hg, and the pulse became imperceptible at 140 to 150. At this stage the woman was quite unconscious. The last reading obtained was: blood pressure 44 mm. Hg, pulse 148; half an hour later death occurred. The series of events took place in the nine hours following delivery. A post-mortem revealed the cause of the progressive shock and only treatment that could have saved this woman would have been the timely removal by laparotomy of the 6 to 8 oz. volume, partially clotted, retroperitoneal effusion in the neighbourhood of the right kidney.

M. K. was another example of persistent fall of pressure after a spontaneous delivery. No loss of blood but coldness, pallor, sweating, and faintness with a pressure of 65, and pulse 132, were present three hours

delivery, in spite of prophylactic treatment. The last readings were blood pressure 50, and pulse 156, the patient being restless, cold, and unconscious, with marked air hunger. Post-mortem examination revealed localized haemorrhagic infiltrations through the lower segment of the uterus, the total volume being 4 to 6 oz. Haematomata were present under the peritoneum, and on the interior of the uterus, over this extravasation.

CONCLUSIONS

In conclusion, there are several points which I wish to emphasize.

As already stated, shock can follow blood extravasation, but this is not inevitable. The necessity for reabsorption was pointed out by Tweedy when he stated that shock would occur when fresh blood came in contact with blood already effused into the tissues.

The first step in the production of shock is a fall in blood pressure, and accordingly as the blood pressure falls to lower levels pulse rate and urinary changes become evident.

A persistently falling blood pressure, in spite of prophylactic treatment, is of very serious import, and efforts should be made in the presence of such readings to localize and remove the blood effusion.

Prophylactic treatment is of the utmost importance, especially the several points already detailed. By its use otherwise inoperable cases will be rendered safe for operation.

In the event of labour not starting after puncture of the membranes, etc., plugging the vagina should be performed without delay, provided that the blood pressure is approximately 80 mm. Hg. Below this level, unless marked improvement in the patient is soon noted, classical Caesarean section should be performed.

I am deeply grateful to the Master of the Rotunda Hospital, who was at all times most anxious to allow the large amount of clinical material under his care to be at the disposal of his assistant.

THE NASAL ELEMENT IN SPASMODIC ASTHMA*

BY

SIR JAMES DUNDAS-GRANT, K.B.E., M.A., M.D., F.R.C.S.

I am convinced that many cases of spasmodic asthma are cured or greatly improved by appropriate intranasal treatment of such abnormalities as may be present. At the same time it must be admitted that some cases are not so benefited.

In many cases of asthma there are nasal abnormalities calling unmistakably for treatment, but similar abnormalities may exist without asthma; while, further, cases of asthma occur in which there are no apparent nasal abnormalities. It follows that whatever importance may be attributable to nasal abnormalities in the production of the asthmatic reflex, there must be some other condition in greater or lesser proportion. It may therefore be asked what the other condition may be, and I think it will be generally accepted that it is something which heightens the sensibility of the vago-accessory centre in the medulla oblongata, producing a condition recognized, with some reservation, as vagotonia.

Dr. Langdon Brown,[1] in his presidential address to the Section of Therapeutics, classifies *the possible excitants* as psychical stimuli, foreign proteins, and peripheral stimuli. It is in the last group that nasal irritation finds itself, along with eyestrain, hay fever and other nasal troubles, sinus infections, gastric and intestinal disturbances, and uterine disorders. The centre may receive sensory stimuli through the sensory divisions of the fifth and those of the tenth nerve. Through the former are conveyed the stimuli aroused by nasal disorders, and through the latter those from the bronchi, the stomach, and other internal organs, derangements of any of which may excite the asthmatic spasm.

In regard to *the psychical element*, we all know of the instance of spasm excited by the presence of an artificial rose, which is only a special case of the effect of expectation so strongly emphasized by Hurst.[2] The existence of a cortical centre for expiration has been proved by the experiments of Horsley and Semon,[3] and there should therefore be no difficulty in explaining the psychical influence which may determine the asthmatic explosion. This centre is closely associated with that for the adduction of the vocal cords and production of voice. In one of my cases in which there was a strong desire to awaken the sympathy of a couple of indulgent parents, and to keep a husband in a state of anxiety, each expiration was accompanied by a vocal sound which was to a great extent voluntary.

Relative hypersensitiveness may be caused indirectly by the removal of cerebral cortical inhibition, and may be supposed to occur in Dixon's experiments, but, as he says, it is doubtful whether it has any significance in the case of the dog. Direct facilitation by a too excitable cortex may produce the same effect, as also may a want of "balance" from defective endocrine action on the sympathetic.

A most important cause of vagotonia is *the anaphylactic action of foreign proteins* producing undue irritability of the vagal centre. Admitting this to be a frequent factor in the asthmatic condition, it is unlikely that it is the only one or an inevitable one. This part of the subject has been thoroughly dealt with by Coke[4] in his exhaustive work on asthma. It appears that only 50 per cent. of cases of asthma answer positively to the skin tests for special sensitization. Drs. Knott and Oriel[5] say that they are not of any clinical value, and Hurst[6] states definitely that except for food proteins in children and also for pollens, they are unsatisfactory. Dr. Adam,[7] in his masterly treatise, holds that overfeeding, especially with farinaceous food, is mainly responsible for the disease we are considering, and treatment founded on this hypothesis appears to be eminently successful. Its importance as a cause is indisputable, both as an excitant of a general toxaemia and a peripheral stimulus through the sensory gastric branches of the vagus. McDonagh[8] says, "Prevent and get rid of familial chronic intestinal intoxication and there would be no asthma." The need for appropriate nasal treatment is at the same time stressed by Adam[9] and by Coke.[10]

While admitting these possibilities, I think there is every reason to attribute a very large share in the

* Read in the Section of Oto-rhino-laryngology at the Annual Meeting of the British Medical Association, Eastbourne, 1931.

production of asthma to the *peripheral stimulation exercised by nasal abnormalities*, as shown by (*a*) the frequency of nasal pathological conditions, (*b*) improvement after their removal, (*c*) recrudescence after their return, (*d*) disappearance of sensitiveness to special irritants after operation, and (*e*) the experiments of Dixon, Brodie, and Ransom.

With regard (*a*) to the *frequency of the presence of nasal disease in cases of asthma* in general, it must be very considerable, as shown by the investigation of 107 cases.[14] In 68 there were nasal changes so well marked as to call for or at least justify operation, in 31 changes so slight that operation was not indicated, in 1 uncertain, and in 7 no nasal abnormality. These seem very high figures, but they were arrived at with every effort made to steer between over-enthusiasm in finding indications for intranasal interference and over-anxiety to avoid operation in which no benefit was likely to result. Making every reasonable allowance for rhinological enthusiasm the proportion is, nevertheless, a high one, and far beyond what simple coincidence would account for. The conditions usually offering themselves to inspection are: abnormally large size of one or other middle turbinated body, hypertrophy of the anterior lip of the hiatus semilunaris, deflection of the septum, especially of its upper part, polypoid outgrowths or typical polypi, suppuration in the antrum or other sinuses.

(*b*) The *disappearance or mitigation of the asthmatic paroxysm after the removal of nasal disease* is now a frequent observation. In a comparatively unselected lot of 120 cases reported with the nearest possible approach to accuracy, there were 33 cases of practical cure and 67 of improvement. Gratifying as these results might be considered, they seemed to me less favourable than my observations of the striking results in individual cases led me to expect. I therefore investigated a consecutive series of seventeen non-hospital cases. Two of them were subjects of neurotic dyspnoea (which recovered), and in the remaining 15 (genuinely asthmatic) the results were: recovery in 9; great improvement in 3, considerable relief in 1; and results unobtainable in 2.

That such a high proportion of good results should be possible in a consecutive series of cases is a strong evidence of the value of intranasal treatment in cases which are as appropriate for it as these happened to be. The particulars were published in the *Practitioner* for December, 1927.

The results of a consecutive series of *cases of asthma in children* persisting even after the removal of tonsils and adenoids are equally striking; it is very rare in such cases to fail to find enlargement of the middle turbinal on one or both sides to a degree which would arrest the attention of even the most sceptical. Out of 18 consecutive cases at Brompton Hospital the results were as follows: complete relief, 14; attacks fewer and less severe, 1, temporary relief (recrudescence after bronchitis and pleurisy), 1; relief (attacks less severe, nose still requiring treatment), 1; no improvement, 1. When this last patient, who had received no benefit, presented herself recently, she was quite free from asthmatic attacks. Short notes of these cases appeared in the [illegible] for February 28th, 1931, p. 468.

[illegible] has been [illegible] *recrudescence of the asthma* after the recurrence of the nasal disease affords further evidence of where the [illegible] and is still us between the two conditions.

Dr Bethel [illegible] *disappearance of sensitiveness to specific irritants* which have [illegible]ly be anticipated as a result of nasal treatment rapidly under[illegible]s a noticeable feature in one of my cases, small and the [illegible] in whom the presence of a cat induced asthma and who, after nasal treatment, was free from asthma and was able to pet a cat without any discomfort. Another boy, who reacted to cake and nuts, could, after operation, indulge in both without inconvenience. Other observers have reported similar occurrences.

(*c*) The *experiments of Dixon*,[11 12] *Brodie*,[11] *and Ransom*[13] demonstrate beyond question the presence of asthmogenic areas in the nose, especially the upper and back part of the septum. Irritation of this region in decerebrated animals produced contraction of the bronchioles, the action failing when the vagus was cut, but returning when the lower part of the cut nerve was stimulated. The nasal disturbance is therefore, *a priori*, a pre-eminent, even if not the only exciting cause of the asthmatic attack.

It has been suggested that it is not the contraction of the bronchial muscle, but a vasomotor dilatation of the vessels that produces the obstruction. This can only form a comparatively small element, as the bronchial mucous membrane is extremely thin and devoid of anything comparable to the erectile or cavernous tissue which produces the nasal obstruction in vasomotor rhinitis.

A remarkable illustration of the effect of nasal stimulation is the contraction of the lungs in the turtle when the posterior nares are rubbed, as observed by Drs Carlson and Luckhardt on the authority of Dr. Mount[15] of the Mayo Institute.

While insisting on the importance of the nasal element, and recognizing that of the other factors, I suggest that our *treatment* should be regulated according to the proportion in which each is found. Thus, if, say, the anaphylactic element is very obvious and the nasal one only slight, our attention should be mainly directed towards the former, but if, as in the majority of the cases that come before me, the nasal element is unmistakable, this should be dealt with discreetly without neglecting the other factors. This is well illustrated by the case of a distinguished actress, referred to me by my late friend Dr. Perkins, in whom the removal of the anterior portion of the left middle turbinal, with a small polypus attached, was followed by a complete and lasting disappearance of her distressing asthma. In this case the nasal factor preponderated over every other. In the case of an elderly lady, a long sufferer from asthma, I found on one side a much enlarged middle turbinal, and on the other a hypertrophic anterior lip of the hiatus semilunaris. I removed both, and heard no more of the patient till I wrote a year later, and learned from her medical attendant that her asthma had disappeared, her health had greatly improved, and her doctor's bill had diminished by 80 per cent.

As my judicially minded friend Dr. McBride went the length of saying in a discussion on asthma in the London Laryngological Society in 1899:

> "In some asthmatics nasal treatment is [illegible] and even desirable, where the conditions are such [illegible] on other grounds operative measures would certainly [illegible] be indicated."

The operation most often called for is the [illegible] of the anterior part of the middle turbinal by [illegible] a snare, after making a snip in the neck of the [illegible] with a Grunwald's punch or, as preferred by Mr Orr, a Struycken's shear. Occasionally, it is an [illegible] anterior lip of hiatus semilunaris which [illegible] removed. This is best shaved off by means of [illegible] probe-pointed bistoury, the detachment of the [illegible] being completed with a snare. Sometimes [illegible] turned punch forceps has to be used to remove [illegible] or projecting residuum. The object to be kept in [illegible] to clear the pathological tissue away from [illegible] the septum with as little removal as possible, [illegible]

may often be best achieved by submucous resection of a deflected portion of the septum itself, most usually in the upper part.

From the above considerations, it is obvious that asthma depends on many diseased conditions, and is in a way rather a symptom than a disease in itself. This may not afford much immediate consolation to the sufferer, but it indicates to the practitioner that it must be analysed and attacked from various sides. If on one side there is failure, an attack may be hopefully made on another, *if undue delay is avoided*. On the strength of the results I have produced, I urge writers on asthma in our textbooks of medicine to place among their foremost instructions that *the nasal condition should be thoroughly investigated and judiciously dealt with.*

A SURVEY OF PROBABLE PROGNOSTIC FACTORS IN THE TREATMENT OF GENERAL PARALYSIS *

BY

W. A. CALDWELL, M.R.C.S., D.P.M.

LIAISON OFFICER, LONDON COUNTY COUNCIL MENTAL HOSPITAL SERVICE

Most of the data on which this paper is based have been obtained from observations made on some 700 to 800 patients who, while under certificate in the London County Council mental hospitals, received malaria, relapsing fever, sapro-vitan, sulfosin, or tryparsamide, or a combination of any of them, together with subsidiary treatment by novarsenobenzene and the like.

SEX OF THE PATIENT

The first factor I wish to comment upon is that of sex. As is well known from the work of Moore, Solomon, and others, the incidence of neurosyphilis in the female is only one-third of that found in the male, although the nervous systems of both, as shown by the relative percentages of spinal fluid abnormalities, are invaded with equal frequency in the early stages of syphilis. This difference is even greater in women who have had one or more pregnancies, and the greater the number of pregnancies the lower the incidence of neurosyphilis. Such being the case it is of some interest to consider if this increased immunity of parous women to the *Spironema pallidum* is helped or enhanced by pyretic treatment. An analysis of the female paretics treated in the London County hospitals reveals the fact that 28 per cent. were nulliparous, 22 per cent. had had a single pregnancy, and the remaining 50 per cent. had had two or more. The discharge rate of these women as a whole was 31 per cent., but the nulliparae only gave a 19.2 per cent. discharge rate, in contrast to a rate of 47.6 per cent. in primiparae and 30 per cent. in multiparae. That is, pregnancy bettered the discharge rate in the ratio of 1 to 2.5 in single pregnancies and in 1 to 1.6 in multiple pregnancies, or, in round figures, pregnancy doubles the chances of a successful remission. In a similar ratio it also increased their chances of improving sufficiently to become useful workers under supervision, although the mortality percentage did not show any marked variation between the three groups.

AGE

Taking age as the next factor, one finds most observers of the opinion that, with the exception of juvenile paretics, the younger the patient the better the prognosis. In a restricted sense this is true, but when dealing with certifiable mental disease one is usually satisfied if the patient reaches a state of remission good enough to justify his discharge from hospital and sufficiently prolonged to allow of his remaining out indefinitely. In general paralysis it is even satisfactory if the patient has a cessation of seizures, a freedom from contractures, and does not become bed-ridden. If the first-mentioned state is accepted, age is not of such paramount importance, for some patients as old as 56 years remit after treatment and have been discharged, while others over 60 years of age definitely improve and become useful institutional workers. I am purposely rather over-emphasizing the probability of improvement occurring after treatment in elderly paretics to counter a policy of *laissez-faire* towards these patients, which is advocated by some authorities. On the other hand, if an approximate return to normality is demanded, then undoubtedly the younger paretic makes the better citizen. In the cases under consideration the discharged patient who was able to resume his or her occupation to the full, and who only revealed mental abnormalities following an exhaustive mental examination undertaken months or years after treatment, had an average age of 37 years, in contrast to the average age of 46 years of discharged patients who, although they could not be justifiably detained in hospital, still required a certain amount of control and guidance by relatives, and in whom deviation from mental normality was easily detectable. Expressed differently, 71 per cent. of the discharged patients who could be regarded as being economically satisfactory were under 40 years of age. This age factor, however, is of little value in assessing the chances of life of a treated paretic, for in this collection of cases the highest relative death rate was found in patients between the comparatively early ages of 36 to 40 years.

TYPE OF CASE

When reviewing the literature which deals with the relative prognosis of the various so-called types of dementia paralytica, one is confused at the lack of uniformity in the findings, and inclined to be sceptical of type as any aid to prognosis. One could easily understand such differences occurring if it were the relative incidence of the types that varied, for national characteristics and temperaments differ in the normal. The discrepancies occur, however, in the relative results of type as compared with type, inclining one to presuppose that there are certain sets of conditions which vary from community to community, thereby affecting the type result of treatment in different centres. As far as this group of cases is concerned, this supposition cannot be substantiated, for between the types there was little variation in such ascertainable conditions as the average age (excluding, of course, juvenile paretics), the age at which infection occurred or its treatment, the incubation period of the neurosyphilis, or the standard of education and the occupation of the patient. True, women were more prone to be of the manic-depressive types, but not more so than the usual tendency of women to develop a manic-depressive psychosis more frequently than the male. It is a fact, however, that different types do vary in their response to treatment. In this country the expansive grandiose paretic is still the commonest, and at the same time gives the greatest relative

* Paper read in the Section of Neurology at the Annual Meeting of the British Medical Association, Eastbourne, 1931.

discharge rate, very closely followed by patients of the manic type. At the other extreme must be placed juvenile and depressed cases. The latter only remit well enough to be discharged with about one-third the frequency of expansive cases, while "stuporose," "simple dementing," and "tabo-paretic" types, which each give very much the same discharge percentage, only do so one-half as frequently as expansive cases. On combining the percentages of discharged and improved patients, one finds that the total is over 50 per cent. in the expansive and manic types, compared with 22 per cent. only in depressed cases. The latter type also gives the highest mortality percentage—nearly three times that of the manic, which of all types seems to have the greatest resistance to both the *Spironema pallidum* and the rigour of the treatment.

REMARKS ON TREATMENT

As is to be expected, there is a definite tendency for early treatment—that is, two to five months after the first manifestation of general paralysis—to give better results, since not only is the discharge rate higher in the earlier months, but the unimproved cases tend to increase proportionately as time elapses, such a tendency being even more marked in the mortality percentages.

It is still a subject for conjecture when dealing with a disease of which the general public is so fully aware and in which, in the large majority of cases, the primary lesion is so easily observable, how infrequently one is able to obtain any history of its occurrence or treatment. It is almost as remarkable that patients who are able to give such a history remit well enough to be discharged twice as often as the others. One doubts whether this is entirely due to the primary treatment, for there is less than a 5 per cent. difference in the results obtained from cases treated with the organic arsenicals alone, or mercury and iodides only. What I have previously termed the incubation period of neurosyphilis—the length of time elapsing from the primary infection up to the development of the first symptoms of general paralysis—averaged in this collection of cases ten to fourteen years, with extremes of two and forty-three years, and, apart from a slightly greater tendency in patients who develop the disease early—that is, from two to six years after the chancre—to remain unimproved, there was no relationship between incubation period and result. Similarly, the quantitative pathological findings in the serum and cerebro-spinal fluids show no relationship to the result. Two points are worthy of comment here. The first is the increased frequency with which one is encountering patients who have a negative serum Wassermann reaction and positive spinal fluid findings, so much so that one is almost inclined to suggest that lumbar puncture should be routine in all new cases admitted to a mental hospital. The second is the ability of both the macro- and the micro-Meinicke reactions to pick out partially treated cases of neurosyphilis when the Wassermann reaction gives a negative result.

Among the factors making for success in the treatment of general paralysis is a short course of tryparsamide before the induction of the pyrexia. This tends to lessen the activity of the cortical spirochaetosis, and allows the patient to rehabilitate his or her general condition and partially eliminate the causes of the toxic disturbances so commonly found in these cases on admission, thus better fitting them to withstand the exhaustion of the fever. The evidence of such improvement is to be found in the increased weight, diminution in the severity of the tremors, and improvement in muscular co-ordination.

Malaria is still our most successful pyretic agent, for, excepting sulfosin and allied sulphur preparations, the introduction of which is of too recent a date for a correct assessment of their value to be made, the other agents are uncertain in their ability to produce any reaction in the organism or, having become effective, are uncontrollable in their course. From a review of this group of cases it appears that one should aim at the production of ten or more pyrexial peaks of 103° or over, while there is some evidence to support the belief that up to an optimum the longer the fever the greater the immunity response. Unfortunately, malaria *per se* has a recognizable mortality rate, but this, as is recommended by the Ministry of Health workers, Horton Mental Hospital, can be controlled to a large extent by the daily enumeration of the number of parasites and the temporary cessation of the fever with small doses of quinine whenever the count gives a higher number than 25 per field.

Again, if the malaria is followed up with novarsenobenzene or sulfarsenol, one may expect a result better by over 10 per cent. than if the treatment consists of malaria alone, while further factors in the continued remission of discharged patients are periodic clinical and serological examinations, accompanied by further treatment with tryparsamide whenever mental or neurological abnormalities present themselves or if the spinal fluid findings show tardiness in reverting to the normal.

SUMMARY

To recapitulate briefly: pregnancy doubles the chances of remission; patients below the age of 40 years make the most economically satisfactory remission, although this should not prevent every patient whose physical state will stand it from receiving treatment quite irrespective of age. In this country expansive and manic paretics give the best prognosis, while depressed and juvenile cases do not respond very satisfactorily to treatment. The ability to remember the primary infection and its treatment is of prognostic value, although neither the length of time elapsing before the onset of neurosyphilis nor the pathological findings are of any value in this respect. Treatment must be thorough, and should be supported by a subsidiary course of organic arsenic after the fever.

TREATMENT OF TRUE RHEUMATOID ARTHRITIS BY BLOOD TRANSFUSION AND INSULIN*

BY

W. S. C. COPEMAN, M.A., M.B., M.R.C.P.

HONORARY PHYSICIAN, BRITISH RED CROSS SOCIETY CLINIC FOR RHEUMATISM; MEDICAL REGISTRAR TO OUT-PATIENTS, ST. MARY'S HOSPITAL

The treatment of true rheumatoid arthritis by orthodox methods yields, on the whole, disappointing results, even when the condition is in an early stage. In this respect it is unlike the other types of arthritis in which the results of proper treatment appear to be in direct relation to the period of the disease at which such treatment is commenced. The treatment here described has been evolved during the last three years, and is an attempt to improve the condition of these patients physiologically by increasing their blood resistance and body weight, since it is assumed that these two factors are the key to the rapid downhill course which is usually observed in these cases.

DEFINITION AND ETIOLOGY

The term "rheumatoid arthritis" is generally used loosely. For the purposes of this paper I refer only to the condition which occurs almost exclusively in

* Based on part of a paper read to the East Suffolk Division of the British Medical Association. Received for publication September 11th, 1931.

young women in the child-bearing period, and which is characterized by lassitude, pallor, loss of weight, and often dyspepsia. The condition commences insidiously, but often runs its course in one or two years, leaving the patient a cripple, the residual ankylosis generally being of a bony nature. The initial lesion appears generally to be a symmetrical, bilateral wasting of the small muscles of the hands, followed shortly by a peri-articular swelling of the mid-phalangeal joints, generally, it seems, of the middle or ring fingers. The metacarpo-phalangeal joints rapidly suffer in similar fashion, as do the wrists, elbows, and feet, if the condition is neglected. As Ray[1] points out, one of the chief characteristics of the established condition is the wasting and atrophy of the skin, muscle, and bone. The skin has a glossy white appearance, and is very transparent. Certain muscle groups tend to waste selectively, particularly extensor groups, and this produces the deformities typical of the condition; the *x* rays show a marked decalcification of the bones, with little other change; the blood nearly always shows a secondary anaemia, while an enlargement of the main lymphatic glands is not unusual.

With regard to the etiology of the condition, very little can be stated with certainty. A toxic focus is generally assumed, but can be located comparatively rarely, while, if such a focus be found, the results of its removal are apt to prove disappointing.

The sex incidence, the age period (which is prior to dental sepsis in most cases), the menstrual disturbances, the symmetry of the lesions, and the intermissions which often occur in its course, are somewhat suggestive of an endocrine disturbance, while the undoubted psychic element which is often present at the onset points in the same direction.

Recently it has been suggested that this condition may have to be classed, in the future, among the "deficiency" diseases.

THEORY OF TREATMENT

If the theory be held that a toxic focus is responsible for the manifestations of rheumatoid arthritis, but at the same time no such focus can be found for removal, the physiological method of dealing with such a case is to increase the antitoxic power of the blood. This is the rationale of vaccine treatment, but this treatment has proved insufficient by itself to deal adequately with these cases, in the experience of most people. The indication would therefore appear to be for an immuno-transfusion, in which the donor is immunized with a specific vaccine prior to giving his blood. This method has been used with some success by Willcox and Dyson in one (unpublished) instance, but in the majority of cases this method would appear to be too cumbersome, in view of the uncertainty with regard to the specific nature of most organisms which might be cultured from the patient, and the necessity for a regular donor. In the present series of cases ordinary large transfusions were employed.

It has been pointed out by Wyatt[2] that one of the most important factors in preparing the soil for rheumatoid arthritis is "under-weight," and it has been stated that the disease never occurs in those whose body weight is up to the average. Since this was considered to be probable, a method was sought whereby these patients could be made to regain their "expected" weight—a very difficult matter in most cases.

It was found that no dietetic measures appeared to have any effect upon the body weight of these patients, who were, on an average, about one stone under the weight which would be expected for their age and height.

Pemberton[3] reported that the sugar tolerance of the rheumatoid arthritic is generally impaired, and although this was in the present instance not found to be an invariable rule, the majority of cases did show a definitely delayed blood glucose curve, without glycosuria.

As a result of these findings it was thought that insulin might be of value in these patients in order to increase the combustion and storage of carbohydrates, and to induce a mild degree of hypoglycaemia before meals, which would lead to an increased appetite, and therefore, it was hoped, to an increase in body weight. These patients generally have very poor appetites, and it is customary to cut down their carbohydrates very considerably. It was found that the use of insulin was, in a majority of cases, instrumental in increasing the body weight, as had been hoped, and that the patients stated that they felt better in every way.

It will be well to consider in turn (*a*) transfusion, (*b*) insulin, and (*c*) the combined treatment, since this was the evolutionary sequence followed clinically.

TRANSFUSION

In sixteen cases which have been reported,[4] ordinary blood transfusions were employed with satisfactory, although never dramatic, results. The patients were taken into hospital and a thorough search made for a toxic focus. In no case among these patients was this found. They were then given a blood transfusion of 500 c.cm., after which intensive physical treatment was given to the affected limbs and muscles on the same day, since the antitoxic power of the patient's blood, if it had been raised by the addition of normal blood, might be expected to be at its maximum at this time. This was repeated every day, and it was found that more treatment could be tolerated than prior to the transfusion. The whole transfusion procedure was then repeated on the eighth day. The citrate method was employed in all these cases, although it is possible that the defibrinated blood method might be more effective, on theoretical grounds. These patients very seldom complained of any reaction, except for a slight headache for a few hours. In two or three cases pain was complained of in the affected joints, lasting a few minutes only, after which the joints remained considerably less painful than previously. This improvement in the pain and in the general condition of the patients (including the appearance of the skin) has been so far maintained for nearly three years in two instances, and for lesser periods in the case of those patients treated subsequently. It was claimed, therefore, that this method of treatment was able to show an advance on other methods in so far as it appeared to arrest the acute course of the disease, and to improve the clinical condition generally. It supplements the more usual methods of treatment, and should in no particular supersede them.

INSULIN

The method adopted is similar to that advocated by Hunt[5] (for cases of visceroptosis), but much higher doses are used. The patient receives initially two injections daily of 5 units of insulin a quarter of an hour prior to luncheon and dinner. The next day 10 units are given in the same way; while on the third day, if no reaction has been experienced, a dose of 30 units is given and continued daily for about three weeks. The patient is not put on a special diet, but is given, as far as possible, what she likes, and is asked to consume, in addition, 1 lb. of glucose in the twenty-four hours. This is best taken as a drink with water or soda-water. It is wise to restrict drinking until after meals. Some of the glucose should be taken last thing at night to prevent any delayed hypoglycaemia occurring during sleep, and a bar of chocolate may, in addition, be eaten after each meal. The course ordinarily lasts for three weeks,

although it may be continued in the out-patient department with one injection daily (according to F. Howitt) for several months, with advantage. Three examples will suffice to demonstrate the type of improvement in the body weight which may be expected in an average case during the initial period of treatment.

Weight Table

Case	Age	Weight on Admission	Date	Weight on Discharge	Date	Increase in Weight	No. of Days of Treatment
		st. lb. oz.		st. lb. oz.		lb. oz.	
L. W.	28	6 12 4	20/5/31	7 2 5	24/6/31	4 1	35
B. L.	24	6 4 0	19/4/31	6 7 0	8/5/31	3 0	28
F. O'R.	54	6 13 1	4/8/31	7 4 3	28/8/31	5 2	24

COMBINED TREATMENT

The best method of dealing with a case of rheumatoid arthritis which fails to respond to ordinary measures appears, as the result of trial in a limited number of hospital cases, to be by a combination of the two preceding methods. No harm will result, and in most cases considerable benefit may be expected. The complete procedure will therefore be as follows.

SUMMARY OF COMBINED TREATMENT SUGGESTED

1. Search for toxic focus; appropriate treatment if found (not forgetting bowel as a "focus").

2. If this produces no improvement, estimate (*a*) the blood sedimentation rate, to see whether a hidden focus of infection is probable, (*b*) the sugar tolerance curve, in view of future treatment with insulin.

3. Place the patient in bed, and carry out the transfusion treatment as described above; two injections at an interval of eight days with intensive physical treatment after each. With nervous patients it is often best to refer to the procedure as a blood "injection," rather than as a "transfusion."

4. Get the patient up on the ninth day. It is important to do this (if she is fit enough) before the psychological effect of the procedure has worn off, particularly with a patient who is almost resigned to being bed-ridden, as is so often the case. The patient must be keen to help, and her co-operation and interest must be sought if the best results are to be obtained.

5. Put the patient on the insulin regime, as described above, and make her weigh herself every day and chart her weight as a curve to stimulate her interest in the method. Most patients will gain about 1 lb. in the first week, and after that about 1 to 2 lb. per week in favourable cases. If the patient has been losing weight prior to the institution of this method, a "latent period" of seven to ten days must be expected before any gain in weight is made. The patient must be cautioned against the expectation of any "miraculous" result, but should be told to expect and report gradual improvement in her general and local condition and weight, the effect on the general health and mental outlook generally being the initial signs of permanent improvement.

THE RATIONAL DOSAGE OF DIPHTHERIA ANTITOXIN

BY

ERNEST GRUNDY, M.B., B.S., M.R.C.S., D.P.H.

Since the introduction of diphtheria antitoxin, many attempts have been made to standardize the dosage of serum, adequate and not excessive, for the different stages and varying degrees of severity of the disease. At one extreme Park[1] suggests that doses of 10,000 to 20,000 units are sufficient for the most severe cases, while Bie[2] maintains that the rational dosage for a severe malignant case should be at least 160,000 to 220,000 units, and, where possible, 20,000 of this should be administered by the intravenous route. In the treatment of cases in which the condition is local and not associated with appreciable toxaemia it is held[3] that antitoxin is of no value, yet although this is probably true, a failure to inject any definite case of diphtheria, even though mild, would lead to difficulties should the infection progress to a more severe stage.

Another point in dispute is that of re-injection of the case after a preliminary injection on diagnosis. Park states: "The injection of a single dose only, of sufficient quantity, is required, and multiple doses, although not harmful, are useless." Friedemann[4] holds that the repetition of large doses is an important factor in the cure of severe cases. It must be almost impossible to judge in advance the requisite dose in all cases, and re-injection must therefore be necessary in some cases at least. The route of administration has been the subject of a good deal of controversy in the past, but since Rolleston[5] pointed out that intramuscular injection is not only more efficacious, but also safer than subcutaneous injection the latter method has become obsolete. Intravenous injection has recently been used, but this method is attended by many dangers in a severely ill and somewhat frightened child, and, unless used immediately, is not so satisfactory as an earlier intramuscular injection. An attempt will be made to show that intravenous injection is not called for.

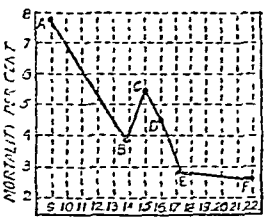
The following table will indicate the diversity of opinion on the subject of necessary dosage.

	Mild	Moderately Severe	Malignant	Large
Park... ...	I.M. 3,000 to 4,000 6,000	I.M. or I.V. 5,000 to 10,000 —	I.V. 10,000 to 20,000 — 40,000	—
Thompson...				
Banks and McCracken	I.M. 14,500	I.V. 19,000 I.M. 19,000	I.V. 71,000 I.M. 31,000	I.V. 2[illegible] I.M. 2[illegible]
Bie	I.M. 16,000 to 20,000	I.M. 64,000 to 80,000	I.V. 20,000 I.M. 140,000 to 200,000	—

I.M.=Intramuscular injection. I.V.=Intravenous injection.

Banks and McCracken, as well as Bie, re-inject after a short period, and, in malignant cases, repeat the injection once or twice according to the needs of the more severe cases. Parks injects all the antitoxin in the primary dose.

In a recent investigation, Bie came to the following conclusions:



1. Diphtheria antitoxin has no effect in reducing the temperature in cases of diphtheria.
2. The membranous condition in the throat frequently spreads after the first injection of antitoxin.
3. Antitoxin hastens the separation of the membrane, but this effect is not marked.

These clinical findings, then, afford no useful data for the determination of an adequate dosage, and, consequently, the percentage mortality of the disease has been chosen in this paper as an index of a satisfactory dosage.

An attempt to correlate the dosage of antitoxin with the percentage mortality from diphtheria in a number of London fever hospitals made it apparent that a relationship existed. The protection conferred by antitoxin is known to vary with the dosage and the day of disease on which the dose is given, but in the consideration of many hundreds of cases admitted to each of several hospitals, it is probable that the average day of disease on which the serum is administered is approximately the same. It would appear, therefore, that any difference in mortality is due to the differences in dosage at the several hospitals, the figures being taken during a non-epidemic period. In the annual report of the Metropolitan Asylums Board,[6] in which are recorded, for each hospital, the total case mortality from diphtheria and also the average primary dose of antitoxin administered to each case on admission, the figures read as follows:

Hospital	Average Primary Dose	Mortality Percentage
A	9,000	7·81
B	13,700	3·84
C	15,000	5·43
D	15,000	4·40
E	17,200	2·87
F	22,000	2·66

The graph below, showing percentage mortality, brings out even more clearly the beneficial effects of the higher dosage (primary dose of antitoxin in 1,000 units).

It is evident, from a consideration of differences in dosage in the various hospitals, that a satisfactory standard of dosage has not been prescribed, or is certainly not widely applied in the infectious hospitals of this country.

An analysis of the exact methods of treatment was undertaken in the two hospitals marked A and F on the graph, and for the purpose of this analysis the cases were divided into three groups.

Group 1.—Malignant

(*a*) Extensive membrane at least on fauces, tonsils, uvula, soft palate, and in the nasopharynx.

(*b*) Cervical adenitis and periadenitis producing bull neck, or this condition on one side.

(*c*) Severe toxaemia amounting at least to hebetude.

Group 2.—Moderately Severe

(*a*) Membrane on both tonsils and on one or both pillars of the fauces and possibly extending to the soft palate.

(*b*) Cervical glands enlarged at least to the size of a walnut.

(*c*) Subdued demeanour, but mental alertness.

Group 3.—Mild

(*a*) Membrane on tonsils and faucial pillars.

(*b*) Glands palpable.

(*c*) Patient somewhat subdued.

Hospital A

During the period under consideration, the average dosage for the various groups of cases was as follows:

Group 1.—Primary injection (intramuscular), 15,400. Total, 27,400 units.

Group 2.—Primary injection (intramuscular), 10,000. Total, 18,000 units.

Group 3.—Primary and total injection (subcutaneous), 4,000 units.

This treatment is almost identical with the recommendation of Park. The high case mortality of 7·81 would appear to show that this dosage is inadequate.

Hospital F

The average dosage used in this hospital was found to be:

Group 1.—Primary injection (intramuscular), 55,000. Total, 145,000 units.

Group 2.—Primary injection (intramuscular), 25,500. Total, 40,500 units.

Group 3.—Primary injection (intramuscular), 14,500. Total, the same.

Remarks

In cases in the first group re-injection was practised after an interval of twelve to eighteen hours, and the serum again introduced by the intramuscular route, usually in doses of 32,000 units. After the second injection, subsequent treatment varied according to the progress of the case. The intramuscular dose of 32,000 units was repeated once or twice on successive days, or, if the faucial membrane showed definite signs of separation, a smaller and final dose was given.

Polyvalent anti-streptococcal serum in doses of 10 to 20 c.cm. was combined in cases showing a marked toxic oedema of the neck, or bull neck, if this condition was thought to be accentuated by invading streptococci. Cases in the milder groups were treated according to the severity of the local condition, but re-injection was never necessary in Group 3 cases, while Group 2 cases usually received only one re-injection of 16,000 to 18,000 units intramuscularly. The use of these larger doses reduced the case mortality to 2·66, including all fatal cases. Those cases where death prevented a full dose of antitoxin being administered are excluded only from the calculation of dosage, and not from the percentage of deaths.

The case mortality of 2·66 has previously been claimed by observers[7] in this country using antitoxin by the intravenous route. If the same protection is conferred by an early intramuscular injection of slightly larger dose, then it would appear to be the more reasonable method of administration, having regard to the possible serious results of the use of the intravenous route.

Conclusions

1. The case mortality in diphtheria varies almost inversely as the amount of antitoxin administered until an adequate dose is reached.

2. The average dosage should be equal to that given in Hospital F.

3. Intramuscular injection of antitoxin is a perfectly satisfactory method of administration.

4. Re-injection of large doses after twelve to eighteen hours, with repetition in malignant cases, is indicated.

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

BUNDLE-BRANCH BLOCK OF VAGAL ORIGIN

The usual causes of bundle-branch block are degenerative lesions of the myocardium, often due to obliterative changes in the small arterioles causing deficiency of blood to the bundle. In younger people syphilis and rheumatism cause a small percentage of cases. Willius[1] gives 4 per cent. as the incidence in cardio-vascular syphilis. In the case described below the striking feature is the constant presence of bundle-branch block, which could be made to disappear temporarily by the injection of atropine. This seems to point strongly to the vagus influence on the heart as, at least in part, responsible for the condition in this subject.

CASE HISTORY

The patient, a girl aged 17 years, was sent by her doctor to consult me at the out-patient clinic at the Liverpool Heart

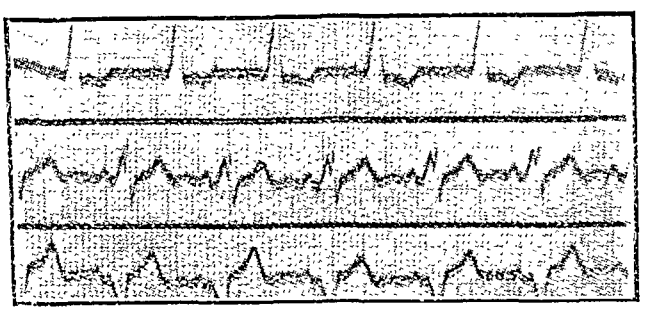

FIG. 1.

Hospital on May 6th, 1930. Her only complaint was infrequent attacks of palpitations since the age of 14 years. The attacks resembled those of paroxysmal tachycardia, beginning and ending abruptly, and lasting from one to fifteen minutes. The attacks sometimes came on while the patient was resting, and at other times on exertion. Between the attacks the patient felt quite well and energetic. There was no dyspnoea on exertion, nor any cardiac pain either between or during the attacks. Apart from a history of acute tonsillitis when 5 years old, there was no history of

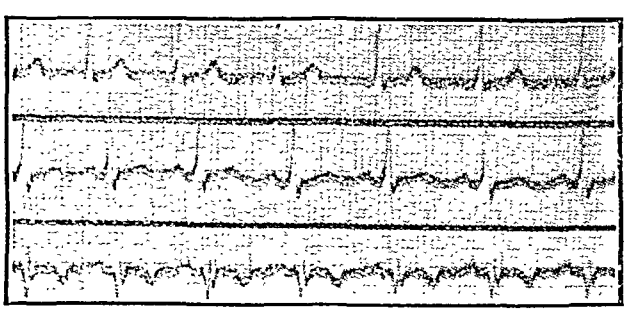

FIG. 2.

any acute illness, of rheumatic fever, of chorea, or of rheumatism. Her family history was unimportant.

Physical Examination.—The patient was of average size and build. There were no signs of anaemia, of cyanosis, or of clubbing of the fingers. The heart examination showed no abnormal signs. The apex beat was normal in position, the heart sounds normal. There was no reduplication of the first or second sound at the apex, no murmurs, nor a bifid visible and palpable apex beat as described by King[2] in cases of bundle-branch block. The *x*-ray picture of the heart showed no abnormality, the orthodiagram being normal in size and shape. The blood Wassermann reaction was negative. The other systems showed nothing abnormal.

Electrocardiographic Records.—On the first examination of the patient on May 6th a routine electrocardiogram was taken, and showed typical right bundle-branch block (Fig. 1). On May 20th a second electrocardiogram was taken, and was similar to Fig. 1; a subcutaneous injection of 1/50 grain of atropine sulphate was then given, and electrocardiograms were taken at intervals of fifteen, thirty, and forty-five minutes after the injection. Fig. 2 shows the electrocardiogram fifteen minutes after the injection of atropine, in which the record is normal, the bundle-branch block having disappeared. The record forty-five minutes after the injection showed the transition back to the bundle-branch lesion. Numerous electrocardiograms were taken for many months after this, and all showed typical right bundle-branch block.

COMMENTARY

A similar case to the above, as far as I can make out in the literature, has never been described. Wilson and Herrmann[3] recorded a case indicating vagal influence in bundle-branch block, but in this the block was transitory, whereas in the above case the block was constantly present except on abolishing the influence of the vagus by the injection of atropine. The fact that the electrocardiogram was converted into a normal record after the injection of atropine shows that the bundle-branch block was not due to organic disease in the bundle with destruction of the tract, but was only effected owing to increased tone of the vagus.

Liverpool. MAURICE NEWMAN, M.D.Liverp., M.R.C.P.

ACUTE APPENDICITIS ASSOCIATED WITH TRANSPOSITION OF VISCERA

The following case is, I consider, sufficiently unusual to be worth publishing.

On July 8th a young woman, aged 21, was admitted to Nenagh District Hospital, at 11 p.m., with a diagnosis of acute appendicitis. About 2 p.m. that day she had been suddenly seized with a severe pelvic pain, which was soon followed by vomiting; this eased after a while, only to return with greater severity after some hours. When seen by me about 12.30 a.m. on the next morning her temperature was 100° F., and her pulse over 100; she had a pain, which was more severe on her right side, but which was felt also in her left side. There was no question of salpingitis, and on the usual examination there was every appearance of acute appendicitis. Rigidity was not marked, and was about equal on either side.

I opened the abdomen immediately by an oblique incision through McBurney's point, and found the right ovary somewhat haemorrhagic, with a pedunculated cyst, which showed signs of torsion. A careful search revealed no sign of appendicitis on that side, and it seemed quite possible that the pain was due to the condition of the ovary. However, it was desirable to inspect the appendix, and further search failed to reveal it in its usual position. I then saw that what I had taken to be the caecum descended into the pelvis, and I immediately suspected transposition of viscera. Further examination revealed that the liver was on the left side, and the heart apparently on the right.

The question now arose whether to close the original incision, after removing the ovarian cyst, and open on the other side, or inspect the appendix from the opening already made. I decided to do the latter, and by extending the incision somewhat could feel a distinct massing of intestines on the left side. Fortunately the appendix proved to be anterior to the caecum, and without much difficulty I brought it into the field of operation. I found the appendix lying in the shape of a U, and very acutely inflamed at the tip. I succeeded in removing it without very much difficulty, and closed the abdomen without drainage.

The patient made an uneventful recovery, apart from a small stitch abscess developing; this cleared up without any trouble, and she is now quite well. I subsequently had her *x*-rayed by Dr. Roche Kelly of St John's Hospital, Limerick, who sent me the following report: "*X*-ray examination with bismuth showed transposition of viscera as follows: heart to the right, liver to the left, caecum [illegible]

[1] Willius, G. A.: *Amer. Heart Journ.*, 1925–26, p. 576.
[2] King, J. T.: Ibid., June, 1928, p. 505.
[3] Wilson, F. N., and Herrmann, G. R.: *Arch. Int. Med.*, 1923, xxxi, 923.

of stomach to the right, pylorus to the left, and caecum to the left, gastro-intestinal tract generally appears normal, except that relations are reversed."

The points of interest in this case appear to be, first, that it is distinctly unusual to encounter an acute appendix in a hitherto undiagnosed case of transposition of viscera. Moreover, the fact that the case presented itself at midnight scarcely helped to simplify matters. The presence of the ovarian cyst on the right side, which had previously given rise to pain, would also tend to obscure the condition. The only point left—namely, not noting the position of the heart—is accounted for by the fact that the patient had a well-developed chest; the heart could be heard quite distinctly on the left side in the examination undertaken by the anaesthetist, and did not attract attention.

I was assisted in the case by Dr. A. W. Courtney, who had sent the patient to hospital.

District Hospital, Nenagh. A. D. COURTNEY, M.B.

Reports of Societies

ANAESTHESIA AND RESUSCITATION

At a meeting of the Section of Anaesthetics of the Royal Society of Medicine on December 4th, with Mr. G. RAMSEY PHILLIPS, president, in the chair, SIR FRANCIS SHIPWAY read a paper on *resuscitation during anaesthesia and of the newly born*.

Anaesthesia, he said, was not sleep, but a state of unconsciousness brought about by the action of depressing drugs or conditions. At times there must be a danger of paralysis of the respiration and circulation. Resuscitation was the restoration of these vital processes. The nervous and muscular activities of the body depended largely on an adequate supply of oxygen and the removal of carbon dioxide excess. The exchange of gases might be interrupted by (1) temporary paralysis of the nervous system owing to lack of oxygen, or action of anaesthetics, (2) paralysis of respiratory muscles, generally secondary to paralysis of the nervous centres, (3) failure of the circulation of the blood.

Artificial respiration supplied the needs of the nervous system and reduced the amount of the anaesthetic present. The alternate expansion and contraction of the lungs produced a mechanical effect by pumping the blood, and brought about the respiratory reflex if the medulla was excitable. If the medulla was paralysed, this phenomenon could not be obtained by artificial respiration alone. In combination with oxygen and enough carbon dioxide to stimulate the centre, artificial respiration was effective. As long ago as 1910, Levi used a mixture of oxygen and 15 per cent. CO_2 when any tendency to failure of respiration occurred. Henderson and Menker stated recently that in the resuscitation of newly born children and of persons suffering from carbon monoxide asphyxia, a carbon dioxide percentage of 7 was often effective when one of 5 had failed. In some cases, 8 or even 10 per cent. was needed to stimulate an asphyxiated respiratory centre. A cylinder containing 7 per cent. CO_2 in oxygen should be available in every operating theatre. Carbon dioxide exerted a powerful influence on the tone of skeletal muscles, and, by augmenting the venous return to the heart, improved the circulation. Care should be taken when mixtures stronger than 10 per cent. were used. A percentage of about 30 produced narcosis and death. In children, failure of respiration was best treated by lowering of the head, partial inversion, rhythmical compression of the chest, and administration of carbon dioxide and oxygen. In the adult, Sylvester's method often failed to restore the respiration; Howard's method was more efficient and less fatiguing, Schäfer's being rarely applicable on the operating table. The use of the latter, however, should be borne in mind in the event of acute respiratory obstruction, under anaesthesia, due to the presence of a foreign body. Occasions might arise when a laryngotomy was necessary, and the forcing of air into the lungs by inflation. Caution was needed against undue violence in carrying out any measure of artificial respiration. When the heart had ceased to beat, attempts to revive it might be made by massage, intracardiac injection of a drug, or puncture of auricle or ventricle.

Many successful cases of restoration by massage had been reported. The route commonly employed was the sub-diaphragmatic. Most attempts, however, were unsuccessful. Bost restored the heart's action, after sub-diaphragmatic massage had failed, by incising the diaphragm and grasping and squeezing the heart. Norbury was unable to restore pulsation in thirteen out of sixteen hearts using sub-diaphragmatic massage, but direct massage, when the abdomen was open, was quickly followed by pulsation. The movements of the hands in this method were those of compression, not of massage. They brought about stimulation of the heart by pressure on the nerve ganglia and by emptying the ventricles.

To prevent pneumothorax, the parts were pressed round the wrist. Levy recommended intubation or passage of an endotracheal catheter so that perflation of the lungs could be effected. The rate of compression should not exceed forty to the minute. The heart usually recovered slowly, and there should be brief intermissions with the first feeble beats. The heart should be stimulated from time to time till the beats became strong and regular. Ogilvie reported a case in which massage was continued for seventy-five minutes before spontaneous beats were obtained. Artificial respiration should be kept up until natural breathing started again. Many drugs had been used for intracardiac injection—caffeine, camphor, digitalis, strychnine, strophanthus, pituitrin, adrenaline, metrazol, and sodium thiosulphate. Imerman revived an elderly patient moribund from insulin hypoglycaemia by injection of 20 per cent. dextrose solution. Adrenaline was the drug most advocated. It was not without danger, as it could produce myocarditis or fibrillary contractions. Success having attended the use of so many different drugs with widely differing actions, it would seem that there was something more at work than the action of the drug. Watson showed in 1887 that in twenty-two out of sixty experiments on dogs killed by chloroform, puncture of the heart alone sufficed to start the beat. Hyman, acting on the view that success of intracardiac injection depended on the irritant action of the needle puncture, succeeded in reviving a patient, collapsed during ether anaesthesia, by puncture of the ventricle after other methods had failed. He stated that the arrested heart became irritable and responded readily to any strong stimulus. The first beats were extrasystoles, usually succeeded by normal rhythm, but if the myocardium had suffered much damage, arrhythmia might persist and develop into ventricular fibrillation. This might explain secondary collapse after successful resuscitation. Extrasystoles arising in the auricles followed by auricular fibrillation were compatible with life. The auricles were more sensitive to stimulation than the ventricles. For these reasons Hyman punctured the auricle in four patients who had died from various causes. In two, the heart-beat was restored, in one for seventeen minutes, and in the other for eight days. Hyman had collected forty-four instances in which auricular puncture had been performed. Out of four patients with healthy asystolic hearts, two responded to the treatment and were still alive. The most

weighty reason for failure was delay in starting resuscitation. Failure did not arise because of inability to restore the heart-beat, but because of damage done to the cortical cells through prolonged interference with their supply of oxygen. It was probable that if the heart-beat was not restored within five minutes, systemic death occurred. Cases of resuscitation, after periods of apparent standstill of ten, eleven, or even fourteen minutes, had been reported, but the time of cardiac arrest was difficult to determine with accuracy. The patient should be given the benefit of the doubt. Unnecessary delay in taking active measures to restore an effective circulation should be avoided, especially if chloroform had been used or the myocardium was known to be degenerated. In Petty's case of recovery after arrest of six minutes, somnolence lasted for twelve hours. Consciousness had not been regained in others, although respiration and circulation were restored for a considerable time. In Mollison's case, the child, who recovered after a period of cessation of the heart's action for at least thirteen minutes, suffered afterwards from the serious damage caused to the cortical cells.

Ventricular fibrillation, under light chloroform anæsthesia, was then discussed, Sir Francis maintaining that Levy had probably overstated the case. Going on to resuscitation of the newly born, the lecturer said that the first essential was to clear the air passages of fluids. This was done by posture or by suction. Mouth to mouth inflation should be kept for emergencies. The child with blue asphyxia should be placed in a warm bath and the skin stimulated by cold douching. If this failed, Schafer's artificial respiration was to be used. With white asphyxia, warmth was most important, and extreme gentleness, with artificial respiration, oxygen, and carbon dioxide. If these failed, direct stimulation of the heart by auricular puncture was to be tried. In some cases, white asphyxia depended not on injury to, or interference with, placental circulation during a difficult labour, but on absorption of an anæsthetic drug from the mother's blood. To meet this a mixture of oxygen and carbon dioxide should always be carried. During all attempts at resuscitation the body temperature of the patient should be maintained.

In the discussion which followed, Dame LOUISE MCILROY described the method which she employed for resuscitation of the newly born. Its main features were warmth, cleansing the infant with oil and no bath, and insufflation of oxygen with 5 per cent. carbon dioxide by a facepiece and bag. A number of other speakers related relevant cases, and took part in the discussion.

SIXTY YEARS OF SURGICAL RETROSPECT

At the December meeting of the Section of the History of Medicine of the Royal Society of Medicine, with Dr. R. O. MOON, president, in the chair, Mr. G. BUCKSTON BROWNE related his surgical experiences during the last sixty years, mainly in private practice. He discussed the almost inexplicable feeling against doctors and surgical science, generally calling it an *odium medicum*, and giving instances of it in the past and present. He dismissed much of it as trivial, but pointed out how grave it was when it ventured to retard research, to interfere with the prevention of disease, and to treat contemptuously the efforts of the medical profession to keep itself pure and honourable by insisting upon proper education, proper qualification, and obedience to its laws and etiquette, the latter all framed in the interest really of the public itself. He gave an account of surgery in London hospitals before the days of Lister, touched upon the progress of anæsthesia, and the rise of the modern nursing home and of the modern nurse. The address ended practically with a plea, that, putting aside very exceptional cases where great difficulties existed, patients with ordinary prostatic retention should have fairly put before them the possibility that if they were content to live the auto-catheter life they might live to be 100, and that the care, punctuality, and moderation of the catheter life itself often seemed actually to prolong life. He pointed out the curious fact that prostatic patients were often remarkable for special abilities, and that their lives were well worth prolonging, even at the expense of a small handicap. The names Mr. Buckston Browne mentioned as specially distinguished during his sixty years of more or less special surgery were Henry Thompson, Clover, Bigelow, Henry Morris, William MacCormac, Garson, and McGill.

Lord MOYNIHAN, who had been McGill's dresser, and had assisted him in his first prostatectomy, said that no one had done anything in prostatectomy that McGill had not done. He described Mr. Buckston Browne as the most prolific ancestor of scientific surgery that this country had ever known, and as one who had created friendships and occasions for conviviality and had done a great deal for the encouragement of research.

Sir JOHN THOMSON-WALKER, in thanking Mr. Buckston Browne for his address, stated that he himself could not claim to have had experience of pre-antiseptic days, but he had been a house-surgeon in the wards of the Glasgow Royal Infirmary next to those in which Lister had done his original work on antiseptics, and had heard many tales from the nurses of the conditions before antiseptics were introduced. Antiseptics were applied to bladder surgery at a later period, and he remembered at the beginning of his hospital work seeing the bladder wounds ulcerated and encrusted with phosphatic deposit, a condition that had now been abolished. Anæsthetics had made great advances since the beginning of the century, and we could now use spinal, rectal, and intravenous anæsthetics either alone or in combination with inhalation anæsthesia. Apart from antiseptics and anæsthesia, progress in the surgery of the urinary organs depended on several factors. (1) The cystoscope, introduced by Mitze in 1886, and brought into use in this country by Fenwick in 1893. To this, many developments, such as catheterization of the ureters, testing the function of each kidney, and pyelography, had been added. (2) The *x* rays, discovered by Roentgen in 1895, and first applied to kidney surgery by MacIntyre, who showed the shadow of a renal calculus in a patient in the Glasgow Royal Infirmary in 1896. (3) Tests of the renal function, the earliest practical work on which was published by Guyon and Albarran in 1898, using methylene blue as the test. We now relied in this country on the urea concentration test, introduced by MacLean and de Wesselow in 1919, and in the combination of this with the estimation of the blood urea. (4) The use of high-frequency currents for destruction of growths in the bladder, introduced by Beer of New York in 1911. It would, he proceeded, be easy to give examples of the progress made by the use of each of these new methods, but one would suffice. Nephrectomy for tuberculosis of the kidney in the decade 1890 to 1900 had a mortality of 25.4 per cent. (Schmieden), while in 1924 and 1927 the mortality was 2.4 per cent. (Wildbolz), and 2.5 per cent. (Thomson-Walker). This was due to the use of the modern methods of diagnosis, and especially of catheterization of the ureters and estimation of the function of the kidneys. Mr. Buckston Browne had expressed some fears of the danger of the cystoscope. He might rest assured that to-day it was a safe instrument of diagnosis in daily use. Electrolysis of stricture was a method which reappeared every ten years or less, only to disappear again into deserved obscurity. But as time went on the number and severity of cases of stricture of the urethra, due to the improved treatment of chronic urethritis, had diminished.

The admission of strictures for operation at St. Peter's Hospital had fallen from about 120 to 20 or 30 a year, in the last twenty years. In regard to the treatment of the enlarged prostate, castration and vasectomy were rightly condemned. But he would not blame White, who first suggested the method, for he did so in the most careful and tentative fashion without any thought of it being universally adopted. The claims for what McGill did in prostatectomy expanded as the years went by, until they embraced every operation performed on the prostate to-day. The speaker preferred to accept McGill's own description of the work clearly set out in his writings up to within three months of his death. It was pioneer's work and the claims were becomingly modest. When Mr. Buckston Browne recommended catheter life in place of prostatectomy, he should not forget the labouring classes. The wealthy, leisured, highly educated classes could command assistance or learn the method of aseptic catheterization in many cases, but to give a labourer a catheter was almost certainly fatal in a very short time.

SURGICAL TUBERCULOSIS IN CHILDREN

At a meeting of the London Association of the Medical Women's Federation, held on November 29th, with Dr. LETITIA FAIRFIELD in the chair, Dr. LOTTE MAHLER of Frankfort read a paper on surgical tuberculosis in children.

Dr. Mahler spoke first of the fundamental conception which must underlie treatment. Tuberculosis, manifesting itself in any organ of the body, was a sign that the tissues of the host had not been able to overcome the bacillus at the portal of entry, and that therefore he must be held to have yielded some ground in the fight against tubercle. It was on that account never permissible to remove a focus without at the same time subjecting the whole body to systematic treatment. The speaker said that she worked in a 2,000 bed hospital, in which certain wards were allocated specially to men, to women, and to children suffering from so-called surgical tuberculosis. It was considered necessary to have special wards for these cases, not only because 60 per cent. of them were found to suffer also from pulmonary tuberculosis, but also, and mainly, because it was necessary to provide facilities for sun treatment, special diet and nursing, and for disinfection. Patients reached them from the medical men in the town, from sanatoriums, and from the other departments of the hospital. The work was done in close contact with the medical consultants and with the follow-up department.

Dr. Mahler enumerated the pathological tests which, with clinical examination and *x* rays, were used for diagnosis. The subcutaneous test was never used for fear of activating the focus. The sedimentation rate of the red blood cells was not considered specific for tuberculosis. Its repeated performance had value, as it enabled observers to note the course of the illness and the results of treatment. A combination of surgical and conservative treatment was now the rule. Good nursing and fresh air, with special diet and sun treatment, were desirable in all cases. Local conservative treatment was designed to stimulate a defensive reaction in the part involved and in the whole body. The best means were sunlight and ultra-violet rays. In the absence of pulmonary tuberculosis, iodine was combined with passive hyperaemia. Soft soap was sometimes used for skin applications. Tuberculin was seldom used therapeutically. Simple orthopaedic appliances were used to support the part affected in such a position as would be most convenient to the patient. Only light fixation was employed, so that small active movements were possible ; disuse atrophy was thus eliminated as far as possible. In after-treatment a splint was used to keep the parts in apposition, or, in case of a leg, to remove the weight of the body. Patients were treated in the out-patient department for some years after leaving hospital. Conservative treatment had to be abandoned in those cases in which it was thought that operation might avoid the risk of amyloid degeneration or in the presence of a severe mixed infection. It was sometimes helpful to remove one focus in order to place the patient in a better position to cope with another. Besides these absolute indications for operation there were some relative ones. In adults, operation was sometimes performed if the condition was such that many years of conservative treatment might be needed. In these cases operation would often restore the patient to his family in a comparatively short time. Operations were also advised if the focus could be removed radically without crippling the patient. Again, if the focus was near a joint, it might be wise to remove it to avoid possible joint infection, with its attendant complications. Each joint had to be considered separately according to its position and functions. In children with joint tuberculosis operations were never performed, even if the process of healing was likely to take many years. In adults, economic conditions might influence the decision in regard to operation, but no such considerations should be allowed in the case of children.

The large majority of patients in Professor Schmieder's clinic, where Dr. Mahler worked, suffered from tuberculosis of the spine. As a rule, conservative treatment was used —that is, the patients were placed on horsehair pillows, built up to fit the normal curves of the spine, with special support to the part involved. Plaster-of-Paris beds were never used. Children were fastened with straps. If there was any sign of irritation of the spinal cord, extension therapy was employed with straps and weights. In this way the muscles could be kept from atrophy, and the skin of the whole body could be exposed to air and sun. When pain and irritation had disappeared, it was easy to turn the patient to a comfortable position on his back or face for some hours every day. Though many years were necessary for the fusion of the destroyed vertebrae, the results were good in the end. Dr. Mahler showed *x*-ray pictures of typical patients to demonstrate that the radical removal of a focus in a vertebra was almost impossible. In the treatment of cold abscesses, incision was avoided if possible. Puncture through healthy tissue and the injection of iodine and glycerin was the method of choice, unless high temperature, in cases of a mixed infection, forced an operation. The injection of lipiodol was useful to enable the track of a cold abscess to be followed. Even in cases of compression of the spinal cord operations were avoided, extension therapy giving better results. In disease of the hip-joint, a board similar to that used at Alton was considered the most effective way of securing immobility. Operation was rarely performed for lesions of the hip-joint, or of the sacro-iliac joint. In the knee-joint cases, young people were treated by conservative methods. In adults, seen only when the joint had already been destroyed, operation gave better results in a shorter time. The patient had a stiff leg, but a useful one. Elbow-joints were treated by conservative methods if in any way possible.

Dr. Mahler referred briefly to tuberculosis of the intestines, glands, and other organs, and described phrenicotomy and thoracoplasty, and methods of cutting and burning adhesions. She described briefly the technique of heliotherapy. A feature of this was the sun garden, open to out-patients. Those who were able to walk could be discharged fairly soon and allowed to go to the sun garden every day, walking back home at night.

Dressings were avoided as far as possible, also plaster of Paris. When the latter had to be used it was blackened on the surface to avoid reflection of light. In this way a higher temperature would be obtained round the parts covered by the plaster, and it was found that the resulting hyperaemia had good effects.

OPERATION FOR GASTRIC DISEASE

At a clinical meeting of the Devon and Exeter Medico-Chirurgical Society, held on November 16th, with the president, Dr. J. R. Harper, in the chair, Mr. R. Wayland Smith showed a series of four cases in which he had recently performed partial gastrectomy.

Carcinoma of Stomach. Married woman, aged 46, with a history of symptoms of peptic ulcer since February, 1931. A large lump could be felt in the epigastrium. Partial gastrectomy (one-third of stomach) was performed. Specimen removed showed a large ulcer with everted edges. Section proved to be epithelioid-celled carcinoma. Progress was satisfactory up to date.

Ulcer of Stomach, Perforated. Man, aged 17. Had had pain every morning for a year, relieved by food. Had noticed definite lump in the epigastrium for two weeks. On November 11th, at operation the portion of stomach removed showed a large ulcer with everted edges. In one place ulcer proved the development of early malignant change. Glandular infection appeared to be slight.

Ulcer of Stomach. Man, aged 47, with four years' history of symptoms, and delay in gastric emptying time noted in 1930. On reading was to hospital, October, 1931, the delay had become extreme, and all symptoms were accentuated. Partial gastrectomy was performed on November 9th, the removed structure showing a non-malignant ulcer of considerable size in the pyloric region.

Ulcer of Stomach. Man, aged 31, with nine years' history of abdominal pain and vomiting. After showing a persistent filling up on the lower curvature on November 11th a V-shaped excision was performed after some difficulty had been experienced in stripping the adherent pancreas from the posterior wall.

Dr. C. J. Fuller read notes on a case of bleeding fissured ulcer of stomach for discussion with Mr. Wayland Smith's cases.

The patient, a man aged 52, came to hospital on October 6th with a 14 months' history of vague dyspeptic symptoms and an account of the passage of a large "black stool" on October 2nd. On admission he was exsanguinated, and died within twenty four hours of admission. The necropsy showed a minute ulcer with the open mouth of a vessel protruding into it.

Dr. F. A. Roper, discussing the indications for operation, as opposed to medicinal treatment and diet, said that the four points emphasized by Mr. Wayland Smith —namely, (1) evidence of stenosis, (2) adherence of the ulcer to a neighbouring viscus, (3) proof of excavation, and (4) relapse after medical treatment—were excellent criteria, and he was in complete agreement with them. Unfortunately, it was by no means easy to diagnose their presence. In the series of cases under discussion these considerations were satisfied, and the radiograph and test-meal findings gave ample justification for operation in each case.

Dr. Fuller said that in deciding upon treatment in cases of gastric ulcer he had found occupation an important factor; for, whereas a leisured man could afford to diet and live carefully for some two years, this was impossible for the working-man, in whom operation was the economical course. Amongst definite indications for operation in all classes Dr. Fuller considered hour-glass stomach, severe haematemesis from a definite ulcer, and adherence to other organs, to be the most outstanding. In the case he had just narrated, operation was contraindicated by the collapsed state of the man on admission; and the condition noted at the necropsy made it seem extremely unlikely that the cause of the haemorrhage would have been discovered before death, even if the condition had justified exploration.

Pseudo-mirror-writing

Dr. Richard Eager showed a case of pseudo-mirror-writing, the subject being an unmarried woman aged 28. She was admitted to the Devon County Mental Hospital for [illegible] and suicidal tendencies, but there was no mention of this peculiarity. It was now known that there was a history of mental deficiency, and that she had been an inmate of public institutions since the age of 20, when she had exhibited the same idiosyncrasies. Examples of writing, the addition of numerical figures, and free-hand drawing, were produced at the meeting, and it was seen that she wrote and drew with the right hand, but that, in distinction to mirror-writing, the girl merely reversed her words, beginning each word from the right instead of the left. Numerical figures, on the contrary, were normal, but drawing was carried out upside down. She was also seen to read up-side down, turning the book clockwise to attain her object. On the other hand, she was found to be unable to read true mirror-writing. When asked to spell a word she responded without hesitation, spelling backwards. Dr. Eager said that in addition to the fits and this hitherto unrecorded abnormality, she had suffered from giddiness, headaches, and imperfect co-ordination.

Dr. Russom Pickard remembered having seen the young woman some eight years before, when the same psychiatrists were in evidence. He said that here was a case where the letters (that is, phonetic constituents) were correct, but the word was reversed—the concept for which the word stood was reversed. In mirror-writing, the word and its constituent letters were reversed as a whole, so that, viewed in a mirror, they conformed to the right-handed conventional writing. If a left-handed mirror-writing child was taught to write successfully in the conventional manner, there was often an intermediate stage in which, while the letters were in the correct order, some of them were still mirrored. In true mirror-writing the phonetic conception was right; hence the essential difference.

EARLY PULMONARY TUBERCULOSIS

At a meeting of the Manchester Medical Society held on November 4th, with the president, Professor J. S. B. Stopford, in the chair, Dr. C. P. Lapage read a paper on early pulmonary tuberculosis in children, dealing with the modern concept of tuberculosis, the diagnosis, and the ideas underlying the B.C.G. inoculation of Calmette.

Dr. Lapage demonstrated some cases of primary infection in young infants (two of them under the care of Dr. J. H. Gibbens) in order to show the primary nodule of infection with satellite glands and the progress either by spread, breaking down and generalization, or by healing and recovery. Radiograms illustrating cases of tuberculosis at the ages immediately following infancy and of hilus tuberculosis at later ages were demonstrated. It was shown that tuberculosis was a very prevalent disease; that infection often took place in the first few years of life and sometimes in the first few months, and that it was often recovered from. Once the child had been infected there followed a period of hypersensibility, and then allergy and resistance were developed. After this infection and resistance the tendency was to localization of disease, and this applied even to a general blood infection. The increased frequency of bacillaemia could now be demonstrated by improved methods. In dealing with diagnosis in early pulmonary tuberculosis, Dr. Lapage said that there was a tendency to decry the clinical examination and to rely on four points: (1) history of infection, (2) positive skin reaction, (3) *x*-ray examination, (4) search for the tubercle bacillus. He insisted strongly that a thorough and complete clinical examination, together with a most careful history of symptoms and signs, were also

of extreme importance, and his criteria for diagnosis of tuberculosis were as follows: (1) careful history of symptoms, including history of infection; (2) thorough clinical examination; (3) *x*-ray examination; (4) search for the tubercle bacillus, including the examination of the contents of the stomach; (5) skin reaction; (6) progress under treatment. Interpretation of skin reaction was mainly that of negation, since it was very doubtful whether gravity of infection and severity of skin reaction were correlated. With regard to Calmette's method of producing immunity by B.C.G., ingestion was preferred, because of the special permeability of the mucous membrane in the early days of life. Statistics pointed to good results, but the explanation of the Lübeck disaster was still being sought. A very large number of babies had been inoculated in many European countries, and Great Britain was certainly behind other countries in regard to the adoption of this method, but Dr. Lapage thought it was probably wise to wait for fuller proof, especially in view of what had occurred at Lübeck. Statistics were not always easy to interpret.

Serum Treatment of Pneumonia

Dr. G. J. LANGLEY read a paper on the serum treatment of pneumonia. Figures from the Registrar-General's returns for mortality from pneumonia were first given, followed by figures supplied from the Health Office of the City of Salford showing the much higher incidence and mortality of pneumonia in the area surrounding Manchester than elsewhere in England. The problem of atmospheric pollution in its relation to the incidence of respiratory diseases was touched upon. Figures were then given, collected from various workers, to show the type incidence of pneumonia in this and other countries, and the figures of Ferguson and Lovell were quoted as indicating the type incidence in Manchester itself. The variation in mortality in different epidemics was shown to be independent of the type incidence of the disease, and was attributed to variations in virulence of the organism itself. It was argued that serum treatment could not as yet be undertaken without adequate typing of the organism concerned for several reasons, difficulty of administration of the serum, and its high cost, being perhaps the chief. Methods of typing which might easily be carried out by the clinician were discussed, and were thought to give no satisfactory results, at least in the early stages of the disease; they were therefore regarded as useless. Sabin's rapid method was considered to be a distinct advance, and, in the few cases in which it had been tried, Armstrong's modification saved a little time; in any case five to six hours were necessarily occupied in this procedure under even the best conditions. Experience with the monovalent Type I serum had not been happy, largely because patients seldom came under treatment early enough in the disease to make success even probable, but also because the large volume of serum used, its frequent repetition, and the occurrence of grave serum sickness were severe handicaps. Dr. Langley then referred to the growing literature on the polyvalent concentrated antibody known as Felton's serum, and compared the British and American records. He considered that estimations of success could only be formed when no-selection alternate case control was rigidly adhered to. In such records as were available, when this had been faithfully done, there was much reason to believe that a very material reduction, both in suffering and in mortality, could be achieved, where the serum was used in adequate doses and early enough in the disease—namely, before the end of the third day. A single case was quoted in which the serum, in large dose, had been used on the sixth day of disease, chiefly on account of a positive blood culture obtained on the fifth day, where an entirely happy issue appeared to justify the procedure.

Reviews

THE PROBLEM OF ALLERGY

Growing interest in the problem of allergy is shown by the recent publication of three books. Dr. G. W. BRAY is to be congratulated on the industry shown in his work.[1] The vast literature of the subject has been well sifted and summarized, while the 1,660 references make the more important original papers readily accessible. The chapters on biochemical aspects and blood changes are particularly good, but, although asthma and hay fever are discussed at length, cutaneous allergy, and the treatment of these conditions, are not dealt with in such full detail. The advances in our knowledge of the biochemical side of the question should enable progress to be made in the near future towards the treatment of allergic states. Clinical observations of these conditions, as Dr. HURST points out in the foreword, now require the help of laboratory investigation, and in this book an account of both will be found. Dr. Bray has produced a work of real value. In brief, it is an accurate summary of the present state of our knowledge, clinical and experimental, and it should prove very useful both to investigators and to clinicians.

Dr. ROWE'S book on *Food Allergy*[2] is of a different type. He has emphasized the importance of food allergy in many symptom-complexes, pointing out that positive skin tests may not be obtained to a particular food, although elimination of that food from the diet brings relief of symptoms. For that reason he has devised "elimination diets" designed to ascertain, by experiment, whether symptoms are due to a particular food or not. The diets are given in detail, together with recipes for their preparation. Ninety-four case histories and twenty-nine tables of statistics are given in the course of 379 pages, thirty-one pages being devoted to a summary of the literature. The subject of food allergy is of great interest, and, on clinical grounds, the author has made out a strong case for his thesis. Experimental evidence is lacking as to the means by which the mechanism of food sensitization is brought about, but possibly none is yet available. It is badly needed; for, as the author points out, patients do not take kindly to restrictions in diet, and some foods, such as eggs, are very difficult to avoid. Specific desensitization as a cure for food allergy does not appear to have been very successful in his experience. As sensitization is usually multiple, in some cases many years might be needed for desensitization to all the foods to which sensitization exists. By Dr. Rowe's "elimination diet," foods responsible for the patient's symptoms may be avoided.

There is evidence that an allergic manifestation depends on a summation of stimuli, so that the more allergens are avoided the less likely are symptoms to occur. Dr. VAUGHAN'S book on *Allergy and Applied Immunology*[3] is designed to assist the allergic patient in understanding what is aimed at for his relief. It gives a clear account of the general principles applicable to the treatment of allergy, and should be easily comprehensible to the intelligent layman, besides being of interest to the medical practitioner. The account of the use of desensitization is especially good, and a clear distinction is drawn between the production of immunity and the process of desensitization. Use of increasing doses of a vaccine to produce

[1] *Recent Advances in Allergy.* By George W. Bray, M.B., Ch.M. With a foreword by Arthur F. Hurst, M.D., F.R.C.P. London: J. and A. Churchill. 1931. (Pp. xii + 432; 98 figures. 12s. 6d.)

[2] *Food Allergy.* By Albert H. Rowe, M.S., M.D. London: Baillière, Tindall and Cox. 1931. (Pp. xi + 442. 25s. net.)

[3] *Allergy and Applied Immunology.* By Warren T. Vaughan, M.D. London: H. Kimpton. 1931. (Pp. 289. 18 figures. 21s. net.)

desensitization in bacterial allergy is condemned. The author brings forward evidence to explain current failure in the treatment of such a condition as rheumatoid arthritis. This is said to result from the employment of too large doses, owing to a confusion about the methods of producing desensitization and immunity.

Each of these three books is well suited to its purpose, and the impression gained is that the results of treatment of allergy have improved considerably in the last few years.

AESTHETIC SURGERY

Pure Aesthetic Surgery (Technique and Results),[4] by RAYMOND PASSOT of Paris, is a small, handy volume of 283 octavo pages. Apart from its intrinsic merit as a book filled with useful information and instruction, it is, we believe, the first publication of its kind devoted exclusively to a subject which is receiving rapidly increasing attention. So far, information on aesthetic surgery—we much prefer the author's adjective to that more commonly used, cosmetic—has been introduced in a fragmentary and half-apologetic manner into works covering the wider subject of plastic surgery. The author is to be congratulated on the excellent case he makes out for a specialty, at one time considered frivolous, of which his experience is obviously wide, for he is able to refer to 2,500 operations for facial wrinkles and 180 operations of an aesthetic nature on the breast. His book is intended for the benefit of practitioners, who, it is felt, should know something about the rudiments of this subject, just as they require a knowledge of the elements of ophthalmology or otology. It is emphasized throughout that aesthetic surgery calls for exclusive specialization, requiring artistic sense, delicate technique, and infinite patience and care over details if mistakes, which cannot be hidden, are to be avoided. Stress is laid on the pronounced psychical effects of physical blemishes and on the gratifying mental improvement which follows correction. A youthful appearance is considered more and more necessary in modern life, for employment often depends on it. It is pointed out, however, that the procedures described are not employed to make old women look young, but to prolong apparent youth in active energetic women who refuse to see themselves looking old before they feel so.

We are glad to see consideration given to the paramount importance of careful diagnosis, to free discussion with the patient of the precise nature of the treatment recommended and the results to be expected from it, and to the particularly important part which dressings may play in this class of work. A warning is given against the tendency on the part of the patient to seek replacement of one extreme by another, and it is aptly stated that Cyrano did not want a Greek nose, but envied the possessor of the retroussé type. We agree that very careful discernment is required if artistic and harmonious results are to be obtained. Local anaesthesia is employed almost exclusively by the author; any serious or lengthy interruption in his patient's routine life is thus avoided. In the chapter on scars, an unusual confidence and optimism is expressed regarding the treatment of keloid scars by excision, followed by immediate *x*-ray or radium treatment. The information about radium therapy is incomplete, for the length of tubes, each containing 10 milligrams of radium element, is not given, and it cannot, therefore, be judged over what length of scar the dose is to be distributed. Further, we do not clearly understand why a shorter exposure should be advised when more than one tube is used in the length of the scar. An oblique arrangement of tubes along a scar would appear preferable to the end-to-end arrangement advocated, if small areas of scar, corresponding to the solid extremities of the tubes, are not to escape radiation.

All classes of nasal deformity are discussed, and the procedures used for correction are well illustrated by diagrams. Paraffin injections are rightly condemned. An interesting description is given of a method of removing lipomata and skin cysts through minimal incisions. Defects of the palpebral fissure, ptosis, lip and ear deformities, facial paralysis, and defects of general facial contour are all dealt with fully, and plastic procedures for the masking of baldness and for the provision of new eyebrows and eyelashes are described. A chapter is devoted to facial wrinkles, and the procedures used for the correction of these, in their different degrees, are well described and illustrated. It is surprising to see local excision advocated for the treatment of double chin, although we realize that by some patients the resulting scar may be thought preferable to the disfigurement. The production of a vertical scar in this region is wisely condemned. The treatment of a certain type of lower eyelid bagginess, by the subcutaneous removal of fat via the lower conjunctival fornix, appears to carry with it too great a risk of infection to justify its inclusion as a purely aesthetic procedure. The author's wide experience convinces him that "face-lifting" procedures exercise a beneficial nutritional influence on the skin. The chapter on breast operations is well constructed, and a full description, helped by many useful diagrams, is given of those procedures employed in the correction of different degrees of prolapse. A useful bibliography and a number of photographic case records are appended.

ARTIFICIAL CRANIAL DEFORMATION

We owe to the great industry and ability of Dr. E. J. DINGWALL an authoritative account of the ethnological aspects of *Artificial Cranial Deformation*.[5] The purpose of the author in this splendid book, which contains five maps, fifty-five plates, a bibliography of over one thousand citations, and an excellent index, is to give a complete and unbiased compilation of the facts that bear on the ethnic aspects of this singular mutilation.

Cranial distortion differs from all other ethnic deformations in that it has obviously nothing to do with initiatic ceremonies or puberty rites, for clearly the deliberate attempt to fashion the skull according to some artificial standard must be begun immediately after birth and continued for the next three or four years. The intentional deformation must of course be distinguished from the accidental results of swaddling the infant or enforcing a prolonged decubitus against some kind of resisting framework, and even the attempts of midwives to massage the skull to close the open sutures. It is true that practices which began as deliberate attempts to mould the head linger on with some spurious justification from the medical opinion of the time. Such rationalizations are at best dubious, for almost invariably the profession at all times has proclaimed the evil of all mechanical restraints to the growing infant. The author's main purpose holds him from discussing at length those aspects of head deformation of more immediate interest to medical science, but from his inquiries it does seem clear that accidental distortions are recovered from almost completely, if not kept up beyond the first year of life. Also all the evidence, despite occasional opinions to the contrary, suggests that even the most extreme deformations, the result of years of restraint, are followed by no untoward effects. Exostoses are not more common in such cases. It is even doubtful if wormian bones are more frequent. There is no reason to believe that

[4] *Chirurgie Esthétique Pure (Techniques et Résultats)*. Par Raymond Passot. Collection des Actualités de Médecine Pratique. Paris: G. Doin et Cie. 1931. (Pp. 283; 80 figures, 8 plates. 45 fr.)

[5] *Artificial Cranial Deformation*. By Eric John Dingwall. London: J. Bale, Sons and Danielsson, Ltd. 1931. (Pp. xvi + 315; 55 plates. £3 10s. net.)

of vision or of smell occur, that intelligence is impaired, or other mental qualities affected

The methods by which the deformation is produced are, of necessity confined to variations in the use of compressing boards and bandages Very impressive is the world distribution of the practice Though no clear case of deliberate deformation of the cranium has been discovered in this country, yet the practice is known in France from Neolithic times onwards to the eighteenth century Without any considerable geographical interval the custom prevails from France through Central Europe to the Caucasus It has existed in Eastern India, Northern India, and Indo-China It can be traced through Melanesia and Polynesia, but apparently did not reach Australia or New Zealand It flares up again in Central America and radiates from there north and south, diminishing in degree and frequency as it passes to the periphery This girdle round the world is joined to Egypt by a pendant in Eastern Europe The author, despite his intentions, naturally returns again and again to the explanation of this bizarre phenomenon Extraordinarily unsatisfactory are such suggestions that the custom is local and sporadic, springing up here and there because of the fundamental unity of the human mind, continued because of the aesthetic impulse, or surviving because it is believed that the practice enhances the intelligence or is conducive to obedience

The genius of Elliot Smith has hit upon an explanation as simple as it is intelligible The author has summarized the evidence which shows that the custom is aristocratic, and that it is the upper classes who deform their heads Apparently this practice began in Egypt, for it so happened that the potent abilities of Akhenaton, the Heretic King, were housed in a skull whose occiput bulged prodigiously—probably the result of hydrocephalus Thereafter the royal family and the courtiers acquire this skull shape by intentional deformation, and Egyptian art which affords no earlier example of this deformity, now depicts it frequently The commerce and the prestige of Egypt spreads the custom and so it slowly extends round the world, often flaring up often dying down, or becoming extinct The chronology of its appearance in various parts of the world, its association with the ruling classes and an abundance of collateral evidence, all combine to support Elliot Smith's theory—a theory rendered more secure by this able and comprehensive monograph of Dr Dingwall

MEDICO CHIRURGICAL PRACTICE

Volumes v to viii of *Pratique Medico Chirurgicale*[6] complete the new third edition of a French medical encyclopaedia, the first four volumes of which were reviewed in these columns on August 22nd (p 345) Although the best wine, in our opinion, has been served last, the criticisms offered upon the work as a whole still hold good It would seem impossible in these days to produce an encyclopaedia of reasonable dimensions which would meet the needs of the family practitioner and at the same time satisfy the specialist, whose clinical and therapeutical field becomes more and more intricate as his interests become more concentrated upon a single subject The omission of the greater part of operative surgery in the next edition would not detract from the value of the present work Those called upon to operate on brain or prostate for instance, go for instruction elsewhere than to encyclopaedias On the other hand, *Pratique Medico Chirurgicale* affords much information to the general practitioner in those discussions of treatment of disease where the medical and surgical possibilities are weighed up and the available methods judicially examined

The volumes before us deal largely on general textbook lines with most of the subject matter, but we would choose the practical and comprehensive sections on syphilis and tuberculosis as outstanding excellencies in an excellent production The sections devoted to obstetrical and gynaecological subjects are most lucid, and the genito-urinary tract is minutely dealt with, the value of the articles being greatly enhanced by beautiful illustrations The pictures of lesions in the bladder as viewed with the cystoscope are perfect in their clarity The attention to detail is exemplified in the description of the passage of catheters—a manœuvre usually passed over in most textbooks

Admirably printed and bound, the volumes will attract the eye and hold the attention of those interested in French medical thought and methods

FAMOUS CENTENARIANS

In *Five Score A Group of Famous Centenarians*,[7] Mr. FORBES GRAY tells in a most readable and attractive manner the life histories of twelve examples of longevity eminent in very different fields As a rule women live longer than men, though it has been said, perhaps by way of consolation, that extreme length of days is less infrequent in the male sex, among the interesting group here presented to the reader three of the sex formerly regarded as the weaker find a place—Lady Smith (1773–1877), the wife of Sir James Smith the botanist Mrs Haldane of Cloan (1825–1925) and the Hon Katherine Plunket, born in 1820 who has more than 110 notches to her not out score The authenticity of these centenarians is well established except in the cases of Charles Macklin *dramatist and actor, the date of whose birth is* doubtful and Martin Routh (1755–1854), the bibliophile and president of Magdalen College, Oxford who died in his hundredth year Only two and these both women, lived beyond 101 years It is rather surprising that the author's diligent search in many likely quarters has failed to reveal more than one medical man who has reached the hundred year mark—Sir Henry Pitman whose autobiography, which constituted much of his obituary notice in the *Lancet* is admittedly drawn on here The account of Manuel Garcia, musician and inventor of the laryngoscope, mentions that he received the degree of doctor of medicine *honoris causa* from the University of Konigsberg A specially interesting life is that of Sir Moses Montefiore, the philanthropist, whose travelling companion, Thomas Hodgkin of Guy's Hospital died at Jaffa, when there with Sir Moses on a mission of mercy during a cholera outbreak *Centenarian representatives of* the Church, diplomacy, the Navy and the Army are also described

BLOOD SUGAR IN CHILDREN

Dr ELISABETH SVENSGAARD has written a monograph in English on *Blood Sugar in Normal and Sick Children*[8] and in particular deals with the metabolism of sugar in coeliac disease She presents a valuable series of data on the fasting level of blood sugar in babies and older children, and its rise after the ingestion of sugar. Unfortunately she appears to use the term hyper-

[6] *Pratique Medico-Chirurgicale* Publiée sous la direction de A Couvelaire, A Lemierre, Ch Lenormant Troisième édition entièrement nouvelle Tomes v, vi, vii et viii Paris Masson et Cie 1931 (1480 fr the set of eight volumes, 165 fr each volume separately)

[7] *Five Score A Group of Famous Centenarians* By W Forbes Gray LRCP FSA Londn J Murray 1931 (12 × 7½, pp 222, 8 plates 12 net)

[8] *Blood Sugar in Normal and Sick Children* By Elisabeth Svensgaard Acta Pædiatrica Vol xi Supplement Uppsala Lewin and Munksgaard 1931 (Pp 240 illustrated)

glycaemia" somewhat loosely for any rise above the fasting level, and writes in the same paragraph of an "extremely slight hyperglycaemia" and a "low blood sugar curve" as synonymous in cases of coeliac disease after ingestion of glucose. Once the terminology has been mastered, however, readers will find this monograph full of useful information. The level of blood sugar in eczema and rickets is also discussed on the basis of a small number of cases. The English is throughout excellent for a foreign writer, although the influence of America is shown in the use of the term "crackers" for biscuits, and the spelling of names is not always accurate, Professor Leonard Parsons having lost his final "s."

NOTES ON BOOKS

The second and revised edition of *A Manual of General Medical Practice*,[9] by Dr. STANLEY SYKES, can be recommended for those who are beginning medical practice. It contains pithy and practical comments on the conditions most likely to be met, and takes for granted such medical and surgical knowledge as the student will have already obtained, thus saving space. It is therefore an eminently readable book, with a satisfactory index and a helpful outlook.

Dr. WILLIAM A. WHITE has contributed a volume (No. 54) to the Nervous and Mental Disease Monograph Series. It is entitled *Medical Psychology: The Mental Factor in Disease*,[10] and surveys the subject generally, though entering into a good deal of detail. The main theme is that disease, wherever occurring, has always a psychological aspect, and that therefore psychology should be just as much an essential part of the medical curriculum as is physiology. The author's arguments and clinical illustrations go far to support this thesis.

Two further Parts—XI and XII—of Baillière's *Synthetic Anatomy*[11] have now appeared. They deal with the male and female perineum in much the same way as previous members of this useful series. In so far as structural and regional anatomy can be taught by pictorial methods, this series is undoubtedly most valuable, but it will probably find its chief use in recalling to the memory of the surgeon, as well as of the medical student, the visual impressions gained by actual study of the human subject.

The *Proceedings of the Second International Congress for Sex Research*,[12] held at the house of the British Medical Association from August 3rd to 9th, 1930, under the presidency of Professor F. A. E. Crew of Edinburgh, have recently been published in a single volume, which is divided into five parts, devoted respectively to biology, hormones, therapy, contraception, and sociology. Of the eighty papers contained in the volume, forty are in English, twenty-one in German, eleven in French, and eight in Italian. Among the papers may be mentioned those on the influence of diet on the procreative faculty of white mice, dogs, and cats, by E. Agduhr; the evolution of secondary sex characters and of accessory sex organs, by J. J. Cunningham; sex differences in the physique of Minnesota University students, by C. H. Jackson; the physiology of sexuality in plants, by F. W. Sansom; biochemical studies on the testicular hormone, by F. C. Koch and A. E. Womack; biological tests of the female hormone, by J. Freud; gynaecology and sexology, by P. Strassmann; constitutional factors in human sterility, by A. W. Rowe; chemical contraceptives, by J. R. Baker; the erotic life of the child, by P. K. Bruhn; and psycho-analysis and biology, by Ernest Jones.

PREPARATIONS AND APPLIANCES

AN IMPROVED TETRA FORCEPS

Dr. ERNEST W. LEWIS (Southport) writes: The tetra forceps in common use have several disadvantages. For instance, the bows, being on the same plane as the teeth, tend to stick up and get in the way of the surgeon. The teeth or jaws are too small, and for this reason are difficult to release from the towel with one hand. The illustration shows an improved model made on my suggestions. The jaws are large, enabling one to apply or remove the forceps with ease. They are a convenient length, shorter than the usual type, the shanks are curved, and the finger-rings are made at right angles to the teeth, so that the forceps lie flat. The jaws being double-toothed, the shanks do not slip about under the tetra cloth.

The forceps have been made for me by the Holborn Surgical Instrument Co., Ltd., 26, Thavies Inn, E.C.1.

CRYSTALLINE VITAMIN D

Calciferol is the name given to pure crystalline vitamin D, as recently isolated by a team of workers at the National Institute for Medical Research (see *British Medical Journal*, November 7th, p. 858). This substance has now been produced on a larger scale by British Drug Houses Ltd., who are offering it for sale. The product has an amazing biological potency, for it contains 40,000 units per milligram. British Drug Houses Ltd. are to be congratulated on having performed a useful service to scientific research by making this substance generally available.

NOVUTOX LOCAL ANAESTHETIC

Novutox local anaesthetic is described as containing para-amino-benzoyl di-ethyl-amino-ethanol hydrochloride and adrenaline in Ringer's solution, with an addition of quinine derivatives and 0.1 to 0.2 per cent. benzoic acid. The first drug is also termed procaine hydrochloride (*U.S.P.*, xi, ethocaine hydrochloride (*B.P.C.*), but is best known under various proprietary names, such as novocain. E. Bergen (*Deut. med. Woch.*, 1929, lvii, 1835) states that novutox contains 1 in 80,000 chinatoxin; he reports favourably on its antiseptic and local anaesthetic action. The makers (Pharmaceutical Corporation Ltd., 39, Aldersgate Street, E.C.1) report bacteriological tests which prove that solutions of novutox remain sterile for weeks after a bottle or ampoule is opened. The advantages and convenience of a local anaesthetic solution that is self-sterilizing are obvious.

A QUININE DERIVATIVE

Thio-quin is a quinine derivative of Indian manufacture (Bio-Technical Works, Ahmedabad). The makers state that its composition is di-hydroxy-trimethoxy-quinine phenyl ester phonate. They claim that it does not produce cinchonism, that it is efficacious as a prophylactic and curative agent in malaria, and that it can be produced at a price which compares favourably with that of quinine. Any advance in antimalarial therapy is a matter of great importance, and we hope that further investigation will substantiate the claims made by the makers.

Nova et Vetera

A DISSERTATION BY WILLIAM HUNTER ON THE UNCERTAINTY OF THE SIGNS OF MURDER IN THE CASE OF BASTARD CHILDREN

Early in the seventeenth century the practice of killing illegitimate children directly they were born had become a very common occurrence The unmarried woman of that time who became pregnant did not resort to illegal operations Abortion then was rare, infanticide quite common Just the converse obtains at the present time —illegal operations being very common, infanticide comparatively rare

THE ACT OF JAMES I

So frequent had the crime of infanticide become that in the reign of James I an Act of Parliament was passed to deal with the matter Briefly, the provisions of the Act were as follows If a woman delivered of a child, which, being born alive, would be a bastard, endeavoured by burying, drowning, or other means, by herself or others, to conceal its birth so that it would not be possible to determine whether it were born alive, it was murder, unless she could prove by one witness at least that it was born dead By this law there was this very important difference between ordinary murder and the murder of a bastard child—that in the latter case the *onus probandi* was in some measure thrown on the accused person, a practice totally at variance with an essential principle of English justice

The law was regarded as so unfair and severe that in practice it seems that judges, juries, and even the prosecution entered into a conspiracy to defeat its harshness

Many fictions and judicial evasions were resorted to in order to evade the Act For example, it was held that if the mother had provided clothes for the expected child she had not concealed the birth, if she knocked on the wall during the actual birth she had called attention to the birth, and again was not guilty of concealment, and so on The Act, however, remained in nominal force till the reign of George III, when in 1803 it was repealed, and it was enacted that trials for murder of bastard children should be taken on the same rules of evidence as in other cases of murder The Act has many interesting features, and some of the relevant portion is here quoted

"And whereas doubts have been entertained respecting the true sense and meaning of a certain Act of Parliament made in England, in the twenty first year of the reign of his late Majesty King James the First, intituled an Act to prevent the destroying and murthering of bastard children, and also of a certain Act of Parliament, made in Ireland in the sixth year of the reign of her late Majesty, Queen Ann, intituled an Act to prevent the destroying and murthering of bastard children, and the same have been found in sundry cases difficult and inconvenient to put in practice, for remedy whereof, be it enacted by the authority aforesaid, that from and after the first day of July in the year of our Lord one thousand eight hundred and three, the said two several Acts, and everything therein contained, shall be, and the same are hereby repealed, and that, from the first day of July in the said year of our Lord one thousand eight hundred and three, the trials in England and Ireland respectively of women charged with the murder of any issue of their bodies male or female, which being born alive would by law be bastard shall proceed and be governed by such and the like rules of evidence and of presumption as are by law used and allowed to take place in respect to other trials for murder and as if the two several Acts had never been made

"Provided always, and be it enacted, that it shall and may be lawful for the jury by whose verdict any prisoner charged with such murder as aforesaid shall be acquitted, to find, in case it shall so appear in evidence, that the prisoner was delivered of issue of her body, male or female, which, if born alive, would have been bastard, and that she did, by secret burying or otherwise endeavour to conceal the birth thereof, and thereupon it shall be lawful for the court before which such prisoner shall have been tried, to adjudge that the prisoner shall be committed to the common gaol, or house of correction, for any time not exceeding two years"

The same Act provides that if any person shall maliciously administer to, or cause to be administered to or taken by any woman, any medicines, drugs, or other substance or thing whatsoever, or shall use or employ or cause or procure to be used or employed any instrument or other means whatsoever, with intent thereby to cause or to procure the miscarriage of any woman not being, or not being proved to be, quick with child at the time of administering such drugs or using such means, such persons shall be guilty of felony, and shall be liable to be fined, imprisoned, set in the pillory, privately or publicly whipped, or transported for any term not exceeding fourteen years If at the time the offence was committed the woman were proved to be quick with child, the punishment was death It was by this Act that the procuring of abortion was first made a statutory offence. Previously, it was punishable by Common Law only.

WILLIAM HUNTER'S VIEWS

The great William Hunter, as the result of his experience in cases of infanticide, believed that injustice was often done to the mothers concerned He gave an address on the subject to the Medical Society in July, 1783, in which he made the following statements

"What is commonly called the murder of a bastard child by the mother is a very different crime if all the circumstances were known In most cases the mother has an unconquerable sense of shame, and pants for the preservation of her character. She has not the resolution to meet and avow her infamy In proportion as she loses the hope either of having been mistaken as regards her pregnancy or of being relieved from her terrors by a fortunate miscarriage she every day sees her danger greater and nearer and her mind more overwhelmed with terror and despair In this situation many of these women would destroy themselves if they did not know that this would infallibly lead to an inquiry and thus disclose their secret. In this perplexity and meaning nothing less than murder of the infant, they are meditating different schemes for concealing the birth of the child They often are taken in labour sooner than they expected, their schemes are frustrated, their distress of body and mind deprives them of all judgement and rational conduct, they are delivered by themselves just where they happen to be, they faint away and on recovering consciousness find the child apparently lifeless. In these circumstances they hide every appearance of what has happened, and do their best to conceal the birth"

Here he mentions several examples, but the lack of space prevents my quoting them But to do the very forcible views of Hunter justice I must relate, even if somewhat fully, one instance

Her scheme was, when taken in labour, to have run out to that house, to be delivered by a midwife who was to have been brought in to her. She was to have gone home after, and to have made the best excuse she could for being out. She had heard of the wives of soldiers having been delivered behind a hedge, and following the husband with the child a short time afterwards. She hoped to be able to do as much herself. She was taken ill at night of a cholic, as she thought; put on some clothes to keep herself warm and that she might be ready to run out if her labour came on. After waiting some time she suddenly fell into such a racking pain and terror that she found she had neither strength nor courage to go downstairs and through the street in that condition, and in the night. In despair, she threw herself on the bed, and by the terror and anguish she suffered she lost her senses and fainted. When she came to a little recollection she found herself in a deluge of discharges, and a dead child lying beside her limbs. She first of all attended to the child and found that it was certainly dead. She lay upon the bed for some time considering what she could do; and by the time that there was a little daylight she got up, put all the wet clothes and the child into her box, and put the room into order.

"Mr. Pinkstan and I declared we thought her tale very credible, and reconciled the circumstances of the swimming of the lungs to the satisfaction of the jury. She was acquitted.

"To form a solid judgement about the birth of a newborn child from the examination of its body a professional man should have seen many newborn children, both stillborn and such as had outlived their birth a short time only, and he should have dissected or have attended dissections of a number of bodies in the different stages of advancing putrefaction.

"I have often seen various common and natural appearances, both internal and external, mistaken for marks of a violent death. The material question, in suspicious cases, is—how far may we conclude that the child was born alive, and probably murdered, if the lungs swim in the water?

"First. We may be assured that they contain air. Then we are to find out if that air be generated by putrefaction.

"Second. To determine this question, we are to examine the other internal parts, to see if they be emphysematous or contain air; and we must examine the appearance of the air bubbles of the lungs with particular attention. If the air which is in them be that of respiration, the air bubbles will hardly be visible to the naked eye; but if the air bubbles be large, or if they run in lines along the fissures, the air is certainly emphysematous, and not air which had been taken in by breathing.

"Third. If the air in the lungs be found to be contained in the natural air vesicals, and to have the appearance of air received into them by breathing, let us next find out if that air was not perhaps blown into the lungs after the death of the infant. It is so generally known that a child born apparently dead may be brought to life by inflating its lungs, that the mother herself or some other person might have tried the experiment.

"If it be clearly made out that the child had breathed, may we infer that it was murdered? Certainly not. It is a circumstance which amounts only to a suspicion.

"If a child makes but one gasp and instantly dies the lungs will swim in water as readily as if it breathed longer, and had then been strangled. A child will very commonly breathe as soon as its mouth is born, and in that case may lose its life before its body be born, especially when there happens to be a considerable interval of time between the birth of the child's head and the protrusion of its body. And if this may happen when the best assistance is at hand, it is still more likely to happen when there is none.

"We frequently see children born who are but barely alive. After breathing a short time they die in spite of all our attention. And why may not that misfortune happen to a woman who is brought to bed by herself?

"When a woman is delivered by herself, a strong child may be born perfectly alive, and die in a very few minutes for want of breath; the following case illustrates this point. A lady at a pretty distant quarter of the town was taken with labour pains in the night time. Her nurse was called up and I was sent for. The child was born before my arrival. It cried and was felt to move vigorously. Expecting to see me every moment come into her bed chamber, and being afraid that the child might be some way injured if an unskilled person should take upon the office of a midwife on the occasion, she would not permit the nurse to touch the child, but kept herself in a very fatiguing posture that the child might not be pressed upon or smothered. I found it lying upon its face in a pool which was made by the discharges, and so completely dead that all my endeavours to rouse it to life proved vain.

"These facts deserve a serious consideration from the public, and as I am under a conviction of mind that, when generally known, they may be the means of saving some unhappy and innocent woman, I regard the publication of them as an indispensable duty."

AN INQUEST OF 1815

The views expressed by Mr. Hunter one hundred and fifty years ago are quite in consonance with modern medical jurisprudence. An account of an inquest held in London in January, 1815, is of interest in connexion with this question. The report is taken from the *Morning Chronicle* of January 24th, 1815.

"Coroner's Inquest. Yesterday evening an inquest was held at the Lion and Lamb, Lower Grosvenor Street, before A. Gell, Esq., Coroner for Westminster, on the body of Sarah Sylvester, a cook in the family of the Rev. Dr. Robert Hodgson, Rector of St. George, Hanover Square, who put an end to her existence by cutting her throat with a razor, in a hay-loft over the stable, in the rear of the house in Lower Grosvenor Street, after having delivered herself of a male child, whose body was found lying near her with a silk handkerchief tied round its neck, and the body covered with hay bands.

"It appeared in evidence, that between 10 and 11 o'clock on Thursday morning the deceased was missed from her master's house. It was then supposed she was gone out on some business of her own, but not returning as the dinner hour drew near, the butler inquired for her at the houses of several persons where she used to frequent, but she was not to be found. Between 7 and 8 o'clock in the evening, the butler and kitchen maid commenced a fresh search for her, and, after looking over every part of the house, they searched the out-offices; on their going up to the loft over the stable, they found the door shut close to; the butler knocked at the door and called, but receiving no answer, he pushed it hard, and found that it was unlocked, but kept shut by something being placed against it on the inside. He forced open the door so far as to admit his head, and looking in, saw the deceased lying against the door with her throat cut, and the floor covered with blood. He turned away horror struck, and made the circumstance known to his master, who sent for Mr. Barrow, a surgeon. Dr. Hodgson, Mr. Barrow, and several of the domestics proceeded to the hay-loft. The deceased was quite dead, with her throat cut from ear to ear, an open razor was lying by her side, and at her feet was the body of a newborn infant, also dead, with a silk handkerchief tied round its neck, and the body wrapped in a hay band.

"No particular acts of insanity on the part of the deceased were laid before the jury, but it appeared that her having the razor in her possession might be accounted for, as it was necessary for the woman to have a sharp instrument for the purpose of delivery; that she might so have it without any idea of committing suicide; and that her pains and the want of proper assistance at the time might bring on a momentary derangement. On the body of the infant there appeared no particular marks of violence, and the jury were led to suppose that the cause of the handkerchief being tied round the child's neck was for the purpose of delivering herself."

The inquiry was long and minute. At length the jury, under the direction of the coroner, returned a verdict of "Suicide whilst of unsound mind," in the case of the woman, and of "Found dead," in the case of the child.

At that time a verdict of suicide carried with it the odium of burial at a cross-road, with a stake driven through the body and forfeiture of goods. The law which was responsible for this horrible procedure was repealed in 1824 (4 Geo. IV, c. 52).

GENITO-URINARY TUBERCULOSIS

In our opening pages this week will be found an interesting account, by Professor A. H. Burgess, of the late John B. Murphy's contributions to urology. Although the name of this prolific worker is associated more particularly with the abdomen, his work in the genito-urinary field of surgery was equally valuable. As not infrequently happens a personal illness first directed his attention to the disease, to the study of which he afterwards made such valuable contributions. Whilst a post-graduate student in Vienna he suffered from a sharp attack of haematuria, which was considered at the time to be due to renal tuberculosis The diagnosis was a mistaken one, but the experience directed Murphy's thoughts not only to the general significance of haematuria, but more particularly to the question of genito-urinary tuberculosis Notwithstanding that he did not possess the many advantages enjoyed by the modern urologist, that the cystoscope was still a primitive instrument, and that such methods of examination as ureteric catheterization and pyelography were unknown, it can be said that the views he arrived at on the subject of urinary tuberculosis differ very little from those held at the present day. Indeed, on only one point would the modern urologist part company with him.

The discovery of a tuberculous focus in a kidney is, according to modern views, a definite indication for nephrectomy, provided the kidney on the opposite side can be certified as sound. It is true that a few workers still maintain, as did Murphy, that spontaneous healing of an early renal tuberculosis may take place, but to the majority, even though they may admit this possibility, the risks of the expectant attitude appear too great to allow of an infected kidney being left, once it is diagnosed. Indeed, there are many who throw doubt on the existence of these cases of spontaneous healing, or consider them so rare that they should not be allowed to influence the plan of treatment. Renal scars are found in the post-mortem room that are uggestive of old healed tuberculous foci, but the proof that they are examples of spontaneous cure is often lacking, or at any rate insufficient to upset the dictum that the only treatment which can free a patient from the risk of a widespread urinary tuberculosis is prompt and early removal But the fact that renal tuberculosis, even in its early stages, is now regarded as a condition that demands surgical intervention does not mean that medical measures play no part in treatment. The removal of the infected kidney is only the initial step, and the adoption of such therapeutic measures as rest, climate, and diet, supplemented, perhaps, by the giving of tuberculin, plays as important a part in achieving a complete and lasting cure of the disease as it did in the days of Murphy. All that can be asked of surgery is that it should rid the patient of tissue that is grossly infected, and place him in a better position to cope with that which has been left behind. The explanation of Murphy's more conservative attitude towards nephrectomy undoubtedly lies in the fact that in his day methods of differential diagnosis were less refined than they are at the present moment. It was difficult, even in the more favourable cases, to be certain that the opposite kidney was sound. If the work of estimating its capacity to support life were handicapped by the existence of tuberculous cystitis and haematuria, the difficulties may well have proved insuperable. In these circumstances a conservative attitude towards nephrectomy would be encouraged, for the danger of removing the wrong kidney, or of leaving the patient with an organ unable to support life, must always have been present Nowadays, however, thanks to the progress made in diagnostic methods, this danger exists only in a small degree, and the surgeon can cut down on a kidney, confident not only that he will find in it a focus of infection, but also that if he removes it the opposite organ is sound and able to maintain the patient in a state of health

But if Murphy, in the light of our present knowledge, erred on the side of conservatism in his treatment of renal tuberculosis, he was certainly right in his attitude to genital infections. As Professor Burgess says, he was a " forceful advocate of the conservative operation of epididymectomy, and strongly opposed to the mutilation of castration " To quote again Murphy's own words, " There is no more occasion for taking out the testis proper in the early stages of tuberculous epididymitis than there would be for taking off the caput coli if you had a case of appendicitis." In this he was most assuredly right, and yet even at the present day there are surgeons who do not hesitate to remove the whole testicle, however early the disease, and however free from infection the body of the testis may be. It would be difficult to justify such a proceeding even if there existed no danger of the opposite epididymis being involved later. When we realize, however, that in over 60 per cent. of cases the disease becomes bilateral within the space of two years, the error is still more flagrant. To the average patient the loss of a testicle comes as a shock, and if a year or two later he discovers that the opposite organ is also involved, he is likely to be plunged into despair. If the epididymis alone has been sacrificed at the first operation, the thought of a second intervention entails little distress, for the patient feels that as he has suffered little or no inconvenience from what has been done before, he can submit to a similar operation with an easy mind Even in cases that cannot be considered early, epididymectomy is all that is necessary, for it is a fact that the testis may remain free from disease even when the epididymis has been converted into a caseous mass This resistance of the testis to invasion, and the tendency for the disease to become bilateral, should therefore always be

uppermost in the mind of the operating surgeon. Indeed, he would do well to assume that even if the epididymis on the opposite side is sound, it will sooner or later become involved, and that for this reason it is advisable to anticipate future trouble and adopt what preventive measures are possible. One of two things may be done: either the sound epididymis may be removed or the vas may be divided between ligatures. Although the former procedure is the more certain, vasoligature, by blocking the path along which the future invasion will take place, affords valuable protection to the epididymis. Some surgeons, and more particularly H. H. Young, have advocated the removal of the entire seminal tract, on the grounds that the testicular lesions are always secondary to a central focus in the prostate and vesicles, and that any operation that does not deal with this central focus is necessarily incomplete. But whether the pathology on which this contention is based be correct or incorrect, there is little clinical evidence that such a wholesale operation is desirable or necessary. It is a matter of general experience that, provided the supply of infected material from the epididymis be cut off, the central lesions in the prostate and vesicles in the vast majority of cases rapidly clear up.

Surgery should not be regarded as the means of eradicating the last trace of tuberculosis either in the genital or in the urinary tract. It is a means to an end, a preliminary to the adoption of medical measures; and in none but the very advanced cases complicated by sinuses is it necessary to include within the sphere of an operation the prostate and vesicles.

THE VIRUS HYPOTHESIS

The somewhat hackneyed title of the imposing volume of 500 pages by Dr. Gye and Dr. Purdy, *The Cause of Cancer*,[1] conceals the fascinating record of six strenuous years of research directed to establish the following propositions: (1) The essential part of the "agent" responsible for the non-cellular transmission of the filterable tumours of the fowl is a living, ultramicroscopic microbe, or virus. (2) The specific characters of non-cellular transmission are due to an associated accessory factor, produced by the tumour cells. Joint action of the two factors, virus and tissue accessory substance, is necessary for infection of new cells. (3) The accessory factor is the same or nearly related in tumours of the same mother cell, and different when cells of a different type are involved. (4) A similar mechanism is responsible for the phenomena encountered in mammalian tumours. If these propositions can be established, cancer can fairly be described as an infective disease, the peculiarities of which depend on the complexity of the mechanism responsible for infection. How far have the authors succeeded in their attempt?

The evidence for the presence of a virus in active filtrates, although still indirect, is very impressive. The close parallel between the mode of action of antiseptics in inactivating tumour filtrates and in killing ordinary bacteria (colon bacillus) or the virus of pleuro-pneumonia is demonstrated at considerable length. (The results of S. L. Baker, not mentioned in the book, on the action of ultra-violet light on *B. coli*, bacteriophage, Rous tumour filtrate, and trypsin, lead to the same conclusion.) The evidence for the complexity of the infecting mechanism occupies the greater part of the book. The fundamental fact requiring explanation is the specific character of the transmission in the absence of living cells. There are now some five or six filterable fowl tumours in existence, which differ among themselves in histology and in biological behaviour, and they all breed true when propagated over long periods by cell-free filtrates. Most of them can also be propagated by injection of completely desiccated tumour tissue after long storage at a temperature a little above 0° C.; and, again, the new tumours reproduce the characters of the parent tumour perfectly and never one of the others. In contrast to this remarkable hardiness the filtrates quickly lose their infectivity on incubation, so that after a few hours highly infective material may be injected into susceptible birds in large doses without result. A careful study of this rapid deterioration by the authors, and by J. H. Mueller, has shown it to be due to the action of tissue oxidases. In consequence it can be retarded by a variety of procedures which inhibit oxidase activity—for example, low temperature, anaerobiosis, dilute hydrocyanic acid, cystein. It is highly improbable that the addition of a cell poison like hydrocyanic acid would lessen the killing effect of otherwise inimical conditions. For this and other reasons the suspicion arose that the loss of infectivity on incubation resulted from the destruction of a labile non-living accessory substance present originally in the active filtrate and necessary for infection.

An account of the authors' efforts to obtain this labile accessory substance entirely free from virus, and to demonstrate its existence and properties in other ways, occupies the second half of the book. The attempts to eliminate the virus by the action of phenol, chloroform, acriflavine, and hydrocyanic acid were carried out in a variety of ways with most elaborate precautions, and the details of the experiments serve as a model for work of this kind. The results were nevertheless inconclusive, and it was impossible to establish experimental conditions under which an accessory factor free from st... viving virus could be prepared with certainty. Th... failure of this line of investigation, and the equivocal nature of the results of experiments in which the re... combination of virus and accessory factor re-te... infectivity, are described with complete candour, and led the authors to attack the problem in another way— by the preparation of antiserums to products contain... the active substances separately or in different a... Active filtrates prepared in all sorts of ways were ... as antigens, either fresh or after heat inactiva... ducks, geese, goats, and horses being employed. T... antiserums, after inactivation by heat, acted in ... ways. Certain tumour filtrates were rendered in ...

lessened in potency, by the heated immune serum alone. Other heated antiserums only acted when fresh normal serum (complement) was added. The inference from general immunological findings was that the first type of action, without complement, corresponded to the action of antitoxic serums on toxins, and showed the presence of the non-living accessory factor. The reaction requiring the presence of complement revealed the presence of an antibody directed against the virus component of the infecting filtrate. An imposing number of experiments of this type were performed, and are recorded in full detail. They cannot be explained on any assumption other than that more than one active substance is present in infective tumour filtrates. Of these, one is made inert by inactivated antiserum, only when complement is present, and its antibody cannot be absorbed by normal fowl tissues. Hence it must be extrinsic and most probably viral. The other is cut out without the assistance of complement. its antibody can be absorbed by normal fowl tissues. Hence it is intrinsic—derived from the cell proteins of the fowl—and not microbic at all.

In regard to proposition (3), evidence that the active component derived from the fowl is the factor responsible for the tissue specificity of the filtrates was not obtained. On the contrary, heated antiserum to Rous sarcoma I, without complement, not only inactivates Rous I filtrate, but also Begg endothelioma filtrate, which is a histogenetically different tumour, but does not inactivate filtrates of Fujinami myxosarcoma, histogenetically identical. In regard to proposition (4), no new evidence of non-cellular transmission of mammalian tumours is adduced.

The charts which accompany the protocols are models of conciseness and clarity. They enable the reader to follow the most intricate arguments without hesitation. A plaintive protest may be permitted at the "art" lettering which mars their legibility. The attack on pathologists and other workers on cancer in the last chapter for their adherence to the "cell theory" of cancer is unjustified and out of place. The hardening of opinion against the virus hypothesis must be attributed much more to the publication of observations in the last few years, claiming an easy demonstration of a microbic etiology of mammalian cancer, than to any ingrained affection for cellular conceptions, physical or chemical. Such conceptions, we believe, are entertained with the reservation that they are subject to revision in the light of new knowledge.

PLAGUE IN 1930-31

The current (September) issue of the *Monthly Epidemiological Report* of the Health Section of the League of Nations contains an instructive survey of the incidence of plague in various countries during 1930 and the first six months of 1931. Generally speaking, the disease was less severe in 1930 than in previous years, this being almost entirely due to the fact that there has been a remarkable diminution in morbidity and mortality in the provinces of British India, which represent the most important foci of plague. In Java and Madagascar alone has the endemic shown no change, while in hardly any other country but Kenya has an increase of the disease been noted. In Northern Africa small epidemic foci have appeared in Morocco (where outbreaks have been known to occur since the end of the eighteenth century), in Algeria, Tunis, Tripolitania, and Egypt. In all these Northern African countries it was possible to distinguish a "maritime" plague (generally of the bubonic type), connected with rat plague in the ports, and a "rural" plague, transmitted either directly from man to man (pulmonary form) or through flea bites (septicaemic and bubonic forms). In Upper Egypt the seasonal variations were well marked, and the peak incidence of plague took place in spring, while in Alexandria the prevalence of the disease is almost constant. In Uganda the incidence of plague is closely related to the development of the cotton industry, so that the victims are most numerous in the districts along the railways where cotton-growing is well established. In the Union of South Africa the principal recent outbreaks of plague have been associated with severe infestations of veld rodents, such as gerbils, hares, and mice. Vaccination with various types of anti-plague vaccine has been carried out on a very large scale throughout Africa during the period under survey. The reduction of plague mortality in British India is shown by the fact that only 23,825 deaths were reported in 1930, as compared with 69,572 in 1929 and 135,647 in 1928. The most striking improvement has taken place in the Punjab, which recently has been second only to the United Provinces in its plague mortality. In Bengal and Assam the disease has been completely absent, and its incidence along the sea coast in the Madras and Bombay presidencies has been comparatively insignificant. In China, plague continues to prevail in several provinces of Manchuria and Mongolia. As regards America, no cases have been noted in the United States since 1928, while in South America the chief foci have been Peru, Argentina, and Brazil, but in none of these countries were the outbreaks extensive. In Europe, plague in 1930 was confined to the Mediterranean Basin, apart from a case reported in Bristol in December in a ship from Novorossiysk, South Russia, and a case at St Ouen, near Paris.

GASTRIC ACIDITY

Dr. J. D. Robertson's monograph on gastric acidity[1] places workers on this subject in his debt for a scholarly study. The function of the stomach is to triturate the food, reducing it to a chyme of uniform consistency for passage into the intestine, and to act on it chemically so as to forward the digestion and solution of the food. Various methods have been used to obtain gastric juice for analysis: opening the stomachs of animals (and even criminals) immediately after death, sponges swallowed and withdrawn later, induced vomiting. Beaumont's observations on his case of traumatic gastric fistula led to a considerable advance in knowledge. The use of the stomach tube mentioned by Boerhaave at the end of the seventeenth century, adopted for cases of poisoning by John Heysham of Carlisle and for dysphagia by John Hunter at the end of the next century, and adapted by Leube a century later for diagnostic purposes is

[1] *Gastric Acidity*. By John D. Robertson, M.D. London: J. Murray. 1931. (8s. net.)

now indispensable in the investigation of gastric disease. Dr. Robertson traces the evolution of our knowledge: first, the verifying that the gastric secretion is acid, and later, the establishing that the predominant acid is hydrochloric acid. Apparently William Prout in 1823 was the first to prove that the gastric juices contained free hydrochloric acid, and, further, that this was the only acid present. This latter conclusion was not, however, generally accepted; for, although it was proved that organic acids were not present in pure gastric juice, a different condition existed when food, especially carbohydrates, entered the stomach. Hydrochloric acid does not appear for some time after the ingestion of food, so that there is time for the action of the ptyalin of the saliva to form lactic acid from the carbohydrate portion of the meal. Many of the experiments on the physiology of digestion were made on dogs, and a dog's saliva has no ptyalin. In man and most other animals which have ptyalin, however, lactic acid is formed during the early stages of digestion. Werner in 1880 pointed out that lactic acid occurred normally in the stomach in the first stages of digestion, and that if found in the later stages in large amounts it constituted a pathological indication, and was due to delay of the ingesta in the stomach, or to insufficiency of hydrochloric acid, which normally inhibits the formation of lactic acid. A new turn to the controversy was given by Ewald, who in 1885 noted a prolongation of the lactic acid phase in pathological conditions, particularly in cancer of the stomach. A few years later Boas claimed that lactic acid was a specific indication of cancer of the stomach, and, further, that it was an early sign. Though Boas afterwards retracted his previous views, and concluded that the production of lactic acid was due to stagnation and deficiency of hydrochloric acid—factors which appear in cancer but which may be present in other conditions as well—some recent writers claim that lactic acid formation is not related to stasis, but is pathognomonic of carcinoma of the stomach, and may arise by the specific activity of the cancer cells in glucose. Dr. Robertson has carried out a series of carefully planned and accurately conducted experiments to settle this question. The material consisted of fractional test-meal examinations of seventy-four consecutive cases at the Middlesex Hospital. The conclusion is drawn that the ordinary qualitative tests and simple reactions for lactic acid are so easily influenced by so many substances that no reliance can be placed on them as a helpful sign in the diagnosis of carcinoma of the stomach. Further careful quantitative tests prove that the absolute specificity of the presence of lactic acid in the gastric contents in cases of carcinoma cannot be upheld. From a chemical analysis of the lactic acid recovered from gastric contents, Dr. Robertson concludes that the lactic acid present is the optically inactive form, of a composition indicating that it is the result of fermentation, and is not sarcolactic acid derived from the body cells. The cases with obstruction had much greater amounts of this lactic acid of fermentative origin. Dr. Robertson's admirable historical and experimental study will have a wide appeal. For many years it was hoped that the test meal would provide a specific chemical diagnosis for various affections of the stomach. Many who were taught to place reliance on the forms of the curves of acidity in various types of gastric disease will be brought up sharply by the author's just conclusion that "careful consideration will reveal the hopelessness of attempting exact mathematical deductions from the analysis of a mixture of food, itself of complex chemical character, saliva, regurgitant duodenal contents, secretions from the mouth, throat, and naso-pharynx."

DIET IN HISTORY

"Diet can have amazing consequences in history" is the *motif* of a recent article by Dr. T. R. Glover, the Public Orator at Cambridge.[1] Diet, he points out, is a factor which has attracted little notice from historians. Sugar, for example, has played a great part in the history of the West Indies and other regions of the world. It was one of the initial causes, though not the only one, of negro slavery in the West Indies, and was at last the supreme cause of the negro remaining in slavery. Thus it came about that slavery spread to the southern colonies in North America, and the cultivation there of rice, tobacco, and subsequently of cotton, was carried on. It was on the question of sugar that the whole struggle for emancipation centred in the days of Clarkson and Wilberforce; and indirectly it was responsible for the American Civil War. Sugar, except in the form of honey, was unknown as a food to the Hellenistic world, though there is some evidence that it was used as a medicine. The sugar cane was early introduced from India into Persia, and was carried by the Arabs to Egypt, Northern Africa, and Spain; the Portuguese introduced it into Madeira; and at the beginning of the sixteenth century it reached the West Indies. Until recent times the question of food chiefly interested historians in so far as it was concerned with famine and bread riots. Herodotus, however, was an exception, for he analysed the regimen of the Egyptians, the "healthiest of men," whose land had no vines, and who would not eat beef. Dr. Glover, referring to the low birth rate of the present day when Gargantuan meals are out of date, reminds the reader of vitamin E (anti-sterility accessory factor) by the remark, "we have paid more attention to food in relation to death than to birth." If it be true, as Timaeus opined, that historians show their own nature in what they linger over, Homer must have been a good trencherman. Athenaeus (circa A.D. 200), who compiled a masterpiece on diet, is described as "a kind of gastronomic Burton, not so pithy, nor so quaint, but as discursive, as learned, and as everlastingly reminiscent of lost authors who discussed the table and its delights, and everything else that might crop up at dinner." In mediæval England meat was poor in quality, and to make it attractive spices and seasoning were much in vogue; but they had to be brought from the East, and this helped to make traders sail far afield, especially the Portuguese and later the Spaniards. Then the Dutch took up the trail, until in an evil hour they so put up the price of pepper and spice that London resented it and established the East India Company. "If our diet affected history, it was surely when bad English meat and high Dutch prices drove Englishmen to find their own pepper."

SIR RONALD ROSS

In *Ronald Ross: Discoverer and Creator*[1] Mr. R. L. Mégroz, who has written other biographies, clearly proves that the popular belief that a man cannot be first-rate in more than one line of work is not without exceptions, and that his hero's record as an all-round genius is remarkable. The author and Mr. Osbert Sitwell (who contributes a brief but highly appreciative preface) both express unqualified admiration for Sir Ronald Ross's literary achievements, not only in poetry, but in prose, his novels, *The Child of Ocean* and *The Spirit of Storm*, not having received the attention they deserve. The first part of the volume is devoted to his activities in medical science and research, especially after the inspiring acquaintance with Patrick Manson; these are set out with sufficient detail to inform the lay reader of the essential facts without entering into too many bewildering technicalities. Working on the basis of Laveran's discovery in 1880, and the part played by mosquitos as carriers of malarial infection, Ross determined to concentrate his work on the study of the malaria parasite in the mosquito rather than in the man, with the triumphant result known to everyone. The original record of the discovery of the malaria parasite in the stomach wall of an anopheles mosquito on August 20th–21st, 1897, is reproduced from the laboratory notebook. In mathematics he was actively interested throughout his career, and long before he took up medical research; his originality was obviously shown in his publications on algebra and equations, the theory of errors and statistics—subjects of use in biological investigation. In the second part of this book his literary works are very fully described in twelve chapters, which present him as a satirical, dramatic, and lyrical poet, and as a critic of life, as a novelist, and as a descriptive writer. The author adds a personal epilogue, illustrated by a photograph of a group celebrating "mosquito day" (August 20th) in 1930. Appendices deal with Sir Ronald Ross's bibliography and other matters. Like other great discoverers he has had to meet opposition, but his name must ever be held in grateful memory.

KING EDWARD'S HOSPITAL FUND

At the annual distribution meeting of King Edward's Hospital Fund for London, held on December 11th, a letter was read from the King, in which he congratulated the council on being able to make a further increase in the distribution this year, and urged the importance of maintaining the income of the Fund and of the voluntary hospitals during the present crisis. The Prince of Wales, who presided, made some introductory remarks about the finances of the voluntary hospitals. In 1930, he said, voluntary contributions reached the remarkable total of £2,900,000 a year in London alone, or £9,000,000 a year for the whole country. Never was it more necessary than at present that there should be no falling off in these contributions. It was an encouraging fact that the ordinary grants made by the Fund had increased from £266,000 to £275,000, and that grants in aid of the pensions scheme were over £19,000. The Fund had been greatly helped by substantial legacies (about £65,000 in each of the past four years), and by special contributions. In addition to those acknowledged at the last meeting, a legacy of £50,000 had been received from the late Sir Otto Beit, and a further donation of £9,000 from an anonymous friend, whose gifts during the last few years now amounted to £63,000. His Royal Highness explained that the Distribution Committee had used the surplus funds available to strengthen the finances of the hospitals which had suffered most in 1930, or which had incurred exceptional liabilities. Commenting on the subject of patients' waking hours, he expressed his satisfaction that the proposals circulated by the Fund had been found feasible in some hospitals, though in the present circumstances it was not easy to make changes that involved additional staff. The Ministry of Health had commended these suggestions to all county councils and county borough councils throughout the country. In regard to the pay-bed insurance scheme for the professional and middle classes (submitted by the British Provident Association in 1929), he gave some striking figures to illustrate the success of the Hospital Saving Association in performing a somewhat similar service for the ordinary hospital patients. Subject to the agreement of the original donors, it was now proposed that £5,000 repaid by that body should be employed to help to launch the British Provident Association. Finally, he referred to the setting up of a special committee of inquiry into the defects of out-patient departments, whose sole object would be to find an impartial solution of the problem that would be accepted and put into operation by all the hospitals. Lord Marshall announced that the League of Mercy proposed to allocate once again to the King's Fund the sum of £17,000 from its collections.

BRITISH POST-GRADUATE MEDICAL SCHOOL: APPOINTMENT OF DEAN

It will be remembered that a provisional organization committee, to proceed with the action necessary to establish a British Post-Graduate Hospital and Medical School at Hammersmith, was set up in July, 1930, and reported last March; and that a Royal Charter constituting the Governing Body of the School was granted in July. The Governors of the School now invite applications from registered medical practitioners for the post of dean, at a salary of £1,800 a year. Applications must be received not later than first post on Monday, February 15th, 1932, by the chairman of the Governing Body, British Post-Graduate Medical School, New Public Offices, Whitehall, S.W.1, from whom further particulars may be obtained.

DEATH OF DR. R. H. TODD

We deeply regret to announce the death of Dr. Robert Henry Todd of Sydney on December 14th. Dr. Todd, who was a vice-president of the British Medical Association, and had for many years been regarded as the centre of medical organization in Australia, was present at the Eastbourne Annual Meeting last summer. He had just returned to Sydney, and intended to come back for the Centenary Meeting. We hope to publish an obituary notice in a later issue.

We regret to announce the death on December 14th, of Dr. James Alexander Lindsay, Emeritus Professor of Medicine, Queen's University of Belfast.

WINTERING IN ENGLAND

CLAIMS OF THE HOME RESORTS

A meeting attended by about eighty members of the medical profession was held at 28, Portland Place, W., on December 9th, to receive and consider a medical statement on the subject of wintering in England, following upon the influentially signed letter which appeared in these columns on December 5th (p. 1059). The chair was taken by Dr. W. G. WILLOUGHBY, President of the British Medical Association, and letters were read from Sir Thomas Oliver, Sir George Newman, Sir Robert Philip, and the Executive Committee of the Bath Division of the British Medical Association endorsing the objects of the movement.

Dr. Willoughby said that the fall of the pound sterling was likely to result in breaking the habit of many people of spending the winter abroad, and the time seemed opportune to put forward the claims of British health resorts, which had never received their proper due. It had been customary in the past to over-acclaim foreign resorts at the expense of British. Yet the British resorts compared very favourably with winter places in the Alps, Riviera, and the Desert. The daily range of temperature, which was a matter of importance to invalids, was 19° in the Alps, 18° at Nice, and 28° at Assouan, as against 7.8° in his own town of Eastbourne, and about the same elsewhere in the South and West of England. Nice had a daily average through the winter months of 3.99 hours of sunshine, but the average length on his own part of the South Coast was 2½ hours—not nearly so great a difference as was popularly imagined. Rainfall for the winter months on British coasts was sometimes a little higher and sometimes a little lower than for Nice. The Desert, to which people were sometimes sent for chest trouble, was overrated. During the war, in January, 1917, he lived for some time in the Desert, and, while the days were full of sunshine, the temperature at night was 44°, representing a difference of 60° between the day and night temperature. On one occasion he went to see a patient in a Swiss sanatorium, and had there not been a mountain railway it would have been impossible to find the spot on account of the prevailing mist. The patient told him that in that month of April there had been only thirteen days on which they had seen the sun at all. The British climate, said Dr. Willoughby, was a mixed one, but it was fitted to the British race, and had helped to make that race what it was. In any statement which went forth from the meeting it was, of course, important to avoid exaggeration, and also to avoid the mention of certain British health resorts at the expense of others. The sunshine records for all the resorts on the coast from Margate to Torquay only varied by small fractions. An important point was to have amenities at these resorts; the British people did not want casinos, but they did want good music and entertainment, and he thought, also, that the hotel people wanted waking up a little.

PROPOSALS FOR ACTION

Dr. FORTESCUE FOX, who has been the leading spirit in this movement, then read a memorandum which the provisional committee had prepared. Various suggestions for revision were accepted at the meeting, and the statement as revised appears below.

Colonel R. H. ELLIOT said that it was not for the medical profession to deal with hotel accommodation, cost of living, and so on, yet those were questions which affected largely the success of the movement towards getting patients to winter in England. British resorts had many advantages, first in respect of good sanitation. Sewage was not poured from our towns on a tideless sea. The food was generally excellent, and one knew what one was eating; it was plainer and better than was met with abroad. The country was a beautiful one, and full of interest of all kinds. The climate in many southern towns was very mild, with a large proportion of winter sunshine. Patients also had the advantage of being within reach of doctors of their own race, and he did not think there were any doctors as good. But patients demanded a greater standard of comfort than had been possible in the average British hotel in the past.

Sir WILLIAM WILLCOX thought the statement a little too restrained. Moreover, the point should be made that for invalids suffering from complaints of a rheumatic nature there were spas in the British Isles which could be well utilized during the winter months. Bath was one of the finest winter spas in the world.

Dr. WATTS EDEN said that although he had at various times sent patients for convalescence to English coast resorts, he had not been very successful. The post-war craze for excitement appeared to affect even the convalescent patient, who declared that he or she would be bored to death at a particular British resort. Somebody ought to write a thesis on the therapeutic value of dullness. For the worn-out mind and body quietude was wanted, with the kind of amusements which could be enjoyed without emotional thrill.

Dr. R. A. YOUNG said that it was possible to envisage great results from this movement on the medical side, but it badly needed the co-operation of the public authorities of the places concerned, the hotel proprietors, and those responsible for the social amenities. In some foreign countries there was available a collective account of their spas, with particulars of their climates and of their provision for visitors, and something of the kind was necessary here. Dr. C. A. MORTLOCK-BROWN urged that sanitation in respect of water supplies and drainage should precede any influx of convalescents into the country side; she had often come across Londoners sent to recruit in areas where there was inadequate sanitation to cope with infectious outbreaks. Dr. COLLIS HALLOWES referred to the desirability of the members of the local profession in each region coming together to decide as to the most suitable spots to send patients. Dr. E. P. POULTON put in a word for the East Coast. He had had a letter from a practitioner in Cromer pointing out that the East Coast was not such a dreary place in winter as was sometimes imagined, and that really uncomfortable winds occurred only in March and April, while the winter sunshine record for Cromer was even higher than for Bexhill. Dr. EGERT MORLAND said that when he was in charge of a foreign health resort a small local committee was established which concerned itself with the conduct of the place from a health point of view. On that committee hotel proprietors and public men, as well as doctors, were represented, and it proved very useful in promoting the amenities of the place. Dr. GEOFFREY HOLMES said that there was already a movement whereby medical men and the municipal authorities in the health resorts of the country were being brought together. One of the difficulties in the whole question was that members of the medical profession in general knew so little of climatology. He suggested that the present movement in favour of wintering in England might well get in touch with the Spa Practitioners Group of the British Medical Association, where an organization would be available for furthering its ends.

APPOINTMENT OF COMMITTEE

After other speakers had addressed the meeting, chiefly with a view to emphasizing the claims of certain localities for inclusion in the statement, the CHAIRMAN said that the suggestions made at the meeting would be duly considered

and a revised statement drawn up. A rather important point was a proposal that there should be regional conferences, perhaps three or four such conferences to cover the coast, where the medical men in the district could meet together and talk over the advantages of the different areas. He thought that such conferences would prove very useful indeed.

The memorandum, amended on the lines suggested at the meeting, was then unanimously approved, and a committee was appointed to carry the matter further. The committee included the signatories to the letter calling the meeting—namely, Sir Farquhar Buzzard, Dr. Watts Eden, Colonel R. H. Elliot, Dr. Fortescue Fox, Sir Thomas Horder, Dr. Robert Hutchison, Dr. E. P. Poulton, Sir Humphry Rolleston, Sir StClair Thomson, Sir William Willcox, Dr. W. G. Willoughby, and Dr. R. A. Young. To these it was proposed to add the name of Dr. King Brown, and also to give the committee power to add to its number, including members representing the coast regions.

MEMORANDUM ON BRITISH WINTER SEASIDE RESORTS

It is impossible at the present time for most people to travel abroad for health, thus gaining complete change of surroundings, mental and physical. But the same benefits in other forms can be obtained in our own country, and the short and comfortable journey to the seaside is often more advisable for invalids and convalescents. Over one hundred marine resorts in this country are now described in the *Medical Directory*. Only a few of these are usually recommended for the winter months; and they are generally regarded abroad as summer places! On the 6,000 miles of British coast there is actually a profusion and variety of places suitable for winter visitors as far as climate is concerned, although many of them are not yet adequately equipped. From the health point of view the coast is therefore an undeveloped asset, to an extent hardly realized either by medical men and the travelling public or the localities themselves.

The object of the present statement is to set forth the values attaching to the various groups of winter marine resorts for the guidance of those who usually winter in warmer climates. The tempering or tonic influences of the sea, at all seasons, give to the seashore definite climatic and medical characters. Marine resorts must therefore always be distinguished from inland health resorts. Only the seaside in the winter season will be here considered.

THE WINTER WARMTH OF BRITAIN

The British seaside resorts differ widely in the quality of the air, aspect, exposure, and winter temperature. Many of them in the south and west have very equable sheltered climates, unaffected by the Polar currents, and protected from easterly winds by intervening land. They lie open to the Atlantic and to the Gulf Stream, which is so effectual a heat carrier that Cape Wrath is as warm in winter as the Isle of Wight. Hence it is that the British Islands enjoy a climate 20° warmer than would be proper to their latitude, as may be judged by the fact that, where shelter is good, in the West, palms and fuchsias, eucalyptus and hydrangeas flourish in the open air.

COMPARISON WITH ALPINE RESORTS AND THE RIVIERA

Comparing the British resorts with winter places in the Alps, Riviera, and the Desert, the average temperature from November to March, the "invalids' winter," is 24° in the Alps, 45° in the South-West of England, 49° at Nice, and 67° at Assouan. The daily range of temperature, a matter of importance for invalids, shows striking differences: it is 19° in the Alps, 18° at Nice, 28° at Assouan, and 8-10° in the West of England.

As compared with the Riviera, the days in England are a little cooler, but the nights are considerably warmer. In place of a sudden fall in temperature at sunset, the Western nights are warm from the protecting clouds. A dry atmosphere, with cold in the Alps or heat in the Desert, is sometimes of definite medical value; but it is also true that the more humid British winter resorts, with great equability of temperature, are very favourable to the preservation and restoration of health. The proportion of sunshine and of daylight cut off by a cloudy atmosphere may differ greatly within a few miles. It often happens that when cloud or fog prevails in London or further north, the day is luminous, with bright sunshine, on the coast. "Fogs are often very localized, sea fogs being more prevalent in summer and land fogs in winter; on the English Channel fogs occur five times more often in June than they do in November, whilst in London land fogs are twenty times more prevalent in December than in June or July" (Hawkins).

THE WESTERN COASTS

This wide area includes the West of Scotland, the coasts of Ireland and Wales and of the Isle of Man, and of the western counties from the Severn to Portland Bill, and has practically an "ocean climate," very temperate and equable. Excepting sheltered places, it is a stormy region, but fogs and mists are uncommon. Among the more interesting wintering places are, in the North-West, Blackpool, Southport, Lytham St. Annes, Douglas, Llandudno, and Colwyn Bay. Further south are Barmouth, Aberdovey, Aberystwyth, and Tenby in Wales; Sidmouth, Exmouth, Teignmouth, and Torquay in South Devon; Falmouth, Penzance, and St. Ives in Cornwall. In the Channel Islands Jersey and Guernsey have slightly higher temperatures, both in the air and sea, as well as longer hours of sunshine. It may be noted that mortality tables in the South-West often show the influence of sheltered climates in prolonging life.

SOUTH AND SOUTH-EAST COASTS

These extend from Portland Bill to the estuary of the Thames. The South is two degrees cooler than the South-West, but more sunny. The southern air is more bracing towards the east—for example, at Brighton, the largest seaside town in England, where the air in winter is strong and invigorating. Worthing is more sheltered, and equally sunny. Further west are Littlehampton, Bognor Regis, Southsea, and Bournemouth, the latter a well-established place for winter visitors. Other wintering places in this region are Ventnor, Swanage, and Weymouth.

In the South-East of England the blending of the sedative western air with the tonic eastern air gives the coast a special quality, well suited for rather robust people, especially children, at all seasons of the year. Westcliff-on-Sea and Hastings, with St. Leonards, have local shelter and aspect appropriate for invalids in winter, especially those with respiratory catarrhs. Eastbourne, with a south-eastern aspect, and Seaford and Bexhill, are more bracing. Clacton-on-Sea and Felixstowe, with their fine air and nearly southern aspect, can be recommended in the early part of the winter, and even the more northern Lowestoft. November and December are often pleasant at the Thanet resorts—Margate and Westgate, Ramsgate and Broadstairs. All the southern places have sunshine records averaging two and a half to two and three-quarter hours per diem from November to March. Many other places not here mentioned have similar climatic advantages.

MEDICAL VALUE OF THE WINTER RESORTS

The seaside has a value for the tired city dweller in winter as well as in summer. It is one of the surest available means of mental and physical refreshment and recovery from slight ailments. In winter-time establishments for recuperative baths are an additional attraction.

Experience has proved particular values of the coast resorts for disordered health. The many disturbances of health which are the precursors of illness in middle life may often be allayed by a right choice of marine climate, with diet, baths, and rest or exercise in pleasant surroundings.

In the south-west a soothing or sedative influence predominates—the breathing becomes easier, bronchial and other respiratory catarrhs are allayed, the action of the skin is encouraged, tissue changes are diminished, the tension of the circulation and nervous stimulation are reduced. Those suffering from fatigue and overstrain are more inclined to rest and sleep. Health resorts having this quality, such as Hastings and Torquay, with its well-appointed medical bath establishment, Falmouth, Weymouth, Sidmouth, Tenby, and

many others, are therefore often chosen for respiratory and circulatory disorders, and for many forms of nervous exhaustion.

There is also in England a group of winter resorts on the south and south-east coasts where the predominating influence is stimulant. The "bracing" quality of the air leads to increased cooling of the body, larger demands on digestion and tissue change, increased activity of the excretory organs and of the heart, and more nervous activity and exercise. The invigorating influence of the sea is especially beneficial after catarrhs and influenza, and in convalescence from serious illness. There is a wide choice of winter resorts of this character, such as Brighton, Eastbourne and Worthing (both with hot sea baths), Bournemouth, Westcliff-on-Sea, Aberystwyth, Colwyn Bay, Lytham St. Annes, and many others.

It is remarkable that simple remedies such as change of air to the coast, with increased daylight and sunshine and the cessation of work and worry, should be sufficient to remove catarrh, to complete the recovery from illness, and even to check the onset of disease. In the summer the open-air life on the shore often meets the needs of health and pleasure, but it must be recognized that the requirements of a winter resort are much more exacting. Although many places have provided the music, social amenities, and entertainments which are necessary for visitors, there is still much to be learnt from Continental resorts in this respect. Pleasant employment and distraction for the mind are necessary in the pursuit of health. Moreover, to make the British coast resorts more generally available, it seems desirable that the cost of accommodation for visitors should be reduced.

In addition to the coast resorts, there are inland spas in the British Islands that can be utilized in the winter months.

INCURABLE CANCER

A METROPOLITAN SURVEY

Some early inquiries made by the Departmental Committee on Cancer gave the impression that a great many women died in London without having availed themselves of existing facilities for hospital treatment. To test the validity of this belief an investigation was made of hospital patients suffering from incurable cancer, the results of which have been published by the Ministry of Health in a report by Dr. Forber—better known as Janet Lane-Claypon.[1] The material was difficult to report on, because the returns covered a number of complex factors, and those from the voluntary hospitals within the selected area fell very short of the numbers anticipated. In the end it was possible to obtain records of 1,983 patients, only about 300 of whom had been in the voluntary hospitals. The area selected was South-East London, and most of the records come from the twenty municipal hospitals of that district. The more important complicating factors in the record were the site of growth and the previous surgical or radiological history of the patient. The inquiry confirmed two familiar features of the cancer problem: the low mortality among women from cancer of the lip, tongue, mouth, and larynx; and the overwhelmingly high relative mortality from cancer of the reproductive organs. The large numbers who had received palliative treatment or an exploratory operation had not been foreseen. When the cases had been divided into classes—(1) recurrence after radical operation; (2) treatment by irradiation; (3) palliative operation; (4) exploratory operation; and (5) no operation or irradiation—it was seen that only 61.3 per cent. belong to Group 5.

TIME AND CHOICE OF TREATMENT

No less than 69 per cent. of all the patients, and probably more, made application in the first place to a private practitioner, by whom they were referred to the voluntary or municipal hospital. Only 206 patients applied direct to the municipal service, twenty-eight being referred by the district medical officer. These figures constitute a striking testimony to the work and place of the general practitioner.

It proved difficult to get a clear answer to the questions: When did the patient first become aware of symptoms? When did he first seek help? and When did he first attend hospital? Generally, more than half the patients who applied to a general practitioner did so within one month of first noticing the symptoms, and of those who applied direct to a hospital about one-third attended within the same period. The data are too inadequate for the report to give definite figures showing the interval which elapsed between visiting a practitioner and being referred by him to a hospital. Since all these patients were incurable by the time they consulted the hospital, and since on the whole they seem to have sought help soon after noticing their symptoms, the conclusion is that cancer of certain sites progresses to a comparatively advanced stage before causing symptoms severe enough to alarm the patient. These figures exonerate the practitioner from the charge sometimes brought against him of delaying under his own care patients who ought to be sent to hospital for more radical procedures. Indeed, the tables show that patients suffering from cancer of the stomach and colon got to hospital rather more quickly if they consulted a private doctor than if they went direct. The only indications of any delay were found in cases of cancer of the rectum and oesophagus.

DURATION OF ILLNESS AND OF IN-PATIENT TREATMENT

In-patient care was available for all applicants at the municipal hospitals without delay; the patient was usually admitted on the day he applied or on the following day. The final stages of the disease are seldom long—hardly longer than those of diseases usually regarded as far more acute. There is also some indication that the duration is shorter in elderly people. The average in-patient treatment in these cases was 2.28 months; for 46 per cent. it was under one month; and only 7 per cent. spent more than six months in hospital.

The average age of death in cases of cancer of the skin and prostate was particularly high, while the mean ages of death from cancer of the lung, uterus, and ovary were low. Generally speaking, cancer attacks the female reproductive organs earlier than it attacks the male organs. A study of the proportions of recurrent and of untreated cases according to the age at death shows that the great majority of untreated cases of cancer of the breast, uterus, and tongue die over the age of 60, and it is approximately true to say that, while from one-quarter to one-third are treated, only from one-quarter to one-third are treated above this age. This may be because old people feel disinclined to face radical procedures, or because they trouble less about their symptoms, or because the disease has a shorter natural duration. It seems likely that the proportion of elderly people treated will increase with the more extended use of radiation.

CURABILITY

All suffering from cancer can be grouped under three heads: those dying without treatment, those "cured" (the standard for which is taken as ten years without recurrence), and those dying within ten years after some form of treatment. The use of the term "incidence" as synonymous with mortality is incorrect, though frequently used. The present inquiry, taken in conjunction with previous publications of the Ministry, makes it possible to group cases of cancer of the breast, [illegible] and uterus in these three classes. For every 100 [illegible]

[1] Janet E. Forber: Incurable Cancer. Reports on Public Health and Medical Subjects, No. 66. H.M. Stationery Office, 1931. Pp. 59. (1s.)

of cancer of the breast which occur, 21 are cured, 48 are treated but die from recurrence, and 31 die untreated. For cancer of the tongue the figures are 9 per cent., 40 per cent., and 51 per cent.; and for cancer of the cervix, 18 per cent., 27 per cent., and 55 per cent. The bases of calculation for the uterus and the tongue are not, however, so reliable as those for the breast.

The report concludes by suggesting three important objects of inquiry: (1) the social services question, Are there adequate nursing facilities in any given area, and to what extent do patients use them? ; (2) the biological question, What is the natural duration of the untreated disease, and what is its relation to the age at onset or at death ? ; and (3) the curative question, What proportion of patients are treated radically, and what are the results ? It is necessary to acquire information of this kind before those concerned with the control of cancer can attempt to cope with that very complex problem on a sound foundation.

France

[FROM OUR OWN CORRESPONDENT]

Depopulation

The congresses are over, and every department of medicine has been discussed. France should now be able to take good care of her population, but, as it was forcibly pointed out at the Congress of Social Hygiene held at Mulhouse, the first necessity is that there should be a population. Exclusive of foreigners the population of France is about 38 millions, roughly the same as it was just before the war of 1870. The population of Germany over this period, however, has increased from 39 to 65 millions, and that of Italy from 25 to 42 millions. The birth rate of France has decreased by more than 30 per cent., and it is probable that it will go on decreasing ; this is partly because of the comparatively small number of births during the war, and partly because the younger generation seems strongly in favour of birth control. A declining population is the greatest danger we have to face. The medical profession is doing its utmost to fight infant mortality, and Dr. Devraigne, well known as an ardent protector of both mother and child, showed us a film, which is to travel throughout France, illustrating the principles of hygiene—the care of the child, hygiene in the home, the consequences of alcoholism, protection against infectious diseases, etc. The congress dispersed after having proposed that the Government should consider all questions connected with ante- and post-natal care of the mother and child as of the first importance, and, further, that taxation should vary in accordance with the number of children in the family. This is yet another example of an error which is common in France—that of appealing to the State rather than to the individual.

The Rat Menace

War was declared against the rat by the delegates from twenty countries who met at the Pasteur Institute. The figures revealed were astounding. In America, year in, year out, the rat destroys agricultural produce to the value of a billion dollars, in England £15,000,000, and in France 200 million francs. A rat consumes 16 lb. of wheat a year, and it has been calculated (not without humour) that under " ideal " conditions, a pair of rats might be responsible for 3,000,000 descendants in one year. Perhaps it is just as well that they are germ carriers, and thus subject to epizootic diseases ; otherwise, in a very short period of time, which could be easily calculated by the mathematician, the whole world—humanity included—would be nibbled away. Most of the methods employed to combat the rat only succeed in driving it over to the next man's barn ; it is therefore of the first importance that this crusade should be an international one. Professor Marchoux, president of the congress, insisted on the necessity of arousing the interest of the whole world and of co-ordinating effort. Dr. Loir relied more especially on the sporting instinct of a special breed of cats which is native to Le Havre, and which seems to have the fighting instinct of the Normans as an innate quality.

Unsuspected Dangers of Butter

Rats are obviously hostile and dangerous to humanity, but if anything looks innocent, is it not that vitamin-provider, butter? Professors Levaditi, Kling, and Lépine, however, have suggested that it takes a share in disseminating infantile paralysis. They have demonstrated by experiments with monkeys that butter is a most successful virus carrier, even after it has been kept at a temperature below freezing point for three months. They conclude that butter should be suspect in cases of epidemics, and that prophylactic measures should be taken. How this is to be done is something of a problem.

A New Medical Unit

The faculty of Medicine at Lyons has been transferred to Grange Blanche, in the suburbs. Two large hospitals are soon to be moved into its immediate neighbourhood—the Charité Hôpital, which is the largest in Lyons, and the Military Hospital, Desgenettes, which is connected with the national military medical school. This will mean an immense saving of time and effort, and is in keeping with the modern tendency towards centralization, but it will be necessary to accustom ourselves to the idea of a hospital city rather than a city hospital. It is hoped that this more up-to-date arrangement, which has been made possible by increased transport facilities, will serve its purpose until transport has been still more simplified, and the carbon-dioxide-poisoned inhabitants of the modern tentacular city can be spread over a much larger area outside the city in which they work. The problem of the hospital will arise once more, of course, but this may be solved by the ambulance aeroplane in the future.

The Psychotechnicist

Efficiency is a compelling force. It is responsible for the creation of yet another specialist in our midst—the psychotechnical doctor. For the first time physicians have been called to the Congress of Technical Teaching, and asked to give their expert advice on the choice of a career. Numerous examples of children born during the war are now met with in the technical colleges. The horrors, the strong emotions, and the sorrows which their mothers experienced during pregnancy have left their mark. They are hypersensitive individuals, who inhibit their emotions, tremble at the slightest remark, however gently spoken, who are tortured by a continual need for useless movement, and whose impulses are often violent. It is necessary to employ mental hygiene and medical treatment in the case of such individuals, because neurotics can be cured if the origin of their malady can be discovered. But it is not only a question of curing or of relieving a malady, but also of economizing effort. The schoolmaster has complained of the intensive efforts required with such individuals and the uncertainty of the results. It must be endeavoured, therefore, in certain cases, to save the schoolmaster from wasting time, to open the eyes of the family to the facts, and to remove the painful confusion which these unhappy individuals must feel in a society for which they are not made. It is here that the advice of the physician is required, and from now onwards the important place which systematic medical investigation must take in technical education, and in all organizations connected with the training of the adolescent, must be realized.

G. MONOD.

England and Wales

London School of Hygiene and Tropical Medicine

At the last meeting of the Court of Governors of the London School of Hygiene and Tropical Medicine, with Sir Holburt Waring in the chair, Sir Harry Goschen, chairman of the Board of Management, in presenting the seventh annual report, said that the School had completed two years' occupation of the new building, and the foundations of the courses of study and of the various research activities of the School had been laid on a sound basis. The dean and the School council were to be congratulated on the year's results as shown by the examinations, particularly in the case of the new university diplomas of bacteriology and public health, and also upon the important developments in the course of study in tropical medicine and hygiene. The Board found satisfaction in having placed clinical tropical medicine on a broader and better-defined basis, in association with the Hospital for Tropical Diseases. In carrying out the programme of teaching and research to which the School had set its hand, it was comforting to learn that the Exchequer grant of £40,000 a year, paid through the University, appeared to be reasonably safe for some time, notwithstanding the present financial emergency. The annual report stated that a Supplemental Charter had been granted to the School, and the amendments embodied therein provided for the addition to the Board of Management of a representative of the Colonial Office, and for the retirement of one-third of the members of the enlarged Board at intervals of three years. The Board had been considering the administration of the School and the functions of the staff. It had recognized as an accepted principle in university institutions that the professors and other teachers on the staff should have a proper share of influence in the management of the work. This end was secured if one of the professors appointed to be dean presided over the deliberations of the School council, and afterwards sat with the Board and took part in its discussions. The Board had decided that the appointment of dean should be held during its pleasure, though, in the first instance, for a period of five years. The dean was to assume the functions hitherto allotted to the director with regard to leave and sick leave, and to have the responsibility for all questions of discipline throughout the School. After adopting the memorandum, the Board had decided to offer the appointment of dean to Professor W. W. Jameson. The death of Sir Andrew Balfour had left a vacancy in the post of director of the division of tropical medicine and hygiene. This appointment was a matter of extreme difficulty, but it would come up for further consideration at an early date. In reporting on the financial position, grateful acknowledgement was made of the help given by the Medical Research Council, the Empire Marketing Board, and the Department of Scientific and Industrial Research. The whole of the research work of the division of epidemiology and vital statistics was financed by the Medical Research Council; the division of bacteriology and immunology also received from the Council a large grant, which was essential for the carrying out of its studies of experimental epidemiology; while the work attaching to the newly founded chair of medical industrial psychology also depended largely on financial aid from the Council. A report of the dean (Professor Jameson) was presented, incorporating the departmental reports. The members of the Court, standing, observed a few moments' silence to do honour to the three great figures in tropical medicine who have passed away during 1931—namely, Sir Andrew Balfour, the first director of the School, and Sir David Bruce and Sir William Simpson, both members of the Court of Governors.

Bristol Medical School Reunion

Under the chairmanship of Dr. Charles Corfield, nearly 150 medical practitioners attended the annual reunion dinner of the Bristol Medical School, held at Clifton last week. In proposing the health of Professor D. C. Rayner, the principal guest of the evening, the chairman said a great many of those present were under an obligation to the professor for teaching them all they knew and helping them out of many difficulties. The high standard of professional conduct set by him, and his personal charm, had done much to win the esteem of all with whom he came in contact. In reply, Professor Rayner said he had been connected with Bristol University for twenty-five years, and could not help comparing the medical school as he first knew it with the wonderful building they now possessed. Great progress had been made during that time, but prestige did not consist entirely of buildings, however magnificent they might be. A much more important asset was the keenness and enterprise of the staff of the opportunities offered, the future of Bristol University would be even more brilliant than its past. The president's health was proposed by Dr. Leonard Moore, and the evening concluded with the handing of the Rugby football cup to Mr. Hughes, captain of the Bristol Royal Infirmary side.

Employment of Married Medical Women by the London County Council

The London County Council at its last meeting had before it a resolution passed by the Medical Women's Federation expressing the firm opinion of that body that marriage should not constitute a bar to the appointment of a woman to any medical post, nor should it be a cause for the termination of her contract; her ability to carry out such a contract should be the only deciding factor. The Council's policy with regard to the employment of married women is embodied in a Standing Order which provides that, with certain exceptions and subject to certain conditions, the marriage of a woman shall put an end to her contract of service with the Council, and married women should be ineligible for employment or re-employment in the Council's service. It was decided to inform the Federation that its protest had been noted, that the Council had a settled policy with regard to the employment of married women, and that, in the Council's view, it would be undesirable to disturb that policy by singling out one section of the staff for differential treatment.

Chief Medical Superintendents of L.C.C. Hospital Service

The late Metropolitan Asylums Board, ten years ago, approved an arrangement whereby three of its medical superintendents, whilst still retaining their posts as such, were appointed "chief medical officers," one for the infectious hospitals service, one for the children's institutions and surgical tuberculosis service, and the third for the medical tuberculosis service. This arrangement has worked well in practice, and the London County Council, which has inherited the institutions of the Metropolitan Asylums Board, has decided that it shall be continued, but that the designation shall be changed to that of "chief medical superintendent." In addition to their ordinary remuneration as medical superintendents, the chief medical officers of the infectious hospitals service and of the children's institutions and surgical tuberculosis service will receive an allowance at the rate of £200 a year, and the chief medical officer of the medical tuberculosis service an allowance at the rate of £125 a year.

Presentation to Dr. J. Yule, Hull

After six years in the public health service of the city and port of Hull, Dr. John Yule, senior assistant medical officer of health, has been appointed medical officer of health to the county borough of West Bromwich. On the eve of his departure, a representative meeting of the Hull health and port sanitary staffs was held in the Council Chamber at the Guildhall, to present to Dr. Yule a mahogany sectional bookcase. The chairman, Dr. N. Gebbie, medical officer of health for the city and port of Hull, said that although he had been in Hull only four weeks, Dr. Yule had in that time rendered him invaluable assistance, which he very highly appreciated. In making the presentation, Dr. Leete, medical superintendent, Infectious Diseases Hospitals, observed that Dr. Yule had, in the course of his experience, covered every phase of public health work, including the transference to the local authority of two large public assistance institutions and hospitals. Other speakers paid tributes to the sterling work and worth of Dr. Yule, who, in thanking all subscribers to the gift, remarked that he would always look back with pleasure to the whole-hearted assistance which had been given him during the past six years. Dr. D. L. Macrae Tod, senior medical officer at the Anlaby Road Institution, extended, on behalf of all sections of the health department staff, a warm welcome to Dr. Gebbie as head of the department.

Scotland

Health of Scotland

The report of the Registrar-General for the quarter ending September 30th, 1931, which has just been issued, shows that the 22,659 births registered during the quarter were 1,463 fewer than in the previous quarter, giving a rate of 18.6 per 1,000 of the population. This is 0.7 per 1,000 below the average rate for the corresponding quarters of the five preceding years. The rates range from 26.9 in Coatbridge, 22.9 in Port Glasgow, and 22.5 in Hamilton, down to 15.8 in Edinburgh, and to 12.4, 12.5, and 12.9 in the counties of Bute, Selkirk, and Peebles respectively. The total births of the quarter included 11,450 male and 11,209 female children. The number of marriages registered in the quarter was 9,351, or 1,193 more than in the previous quarter. With regard to deaths, the number during the quarter was 13,242, or 2,676 fewer than those recorded in the previous quarter. The death rate was 10.8 per 1,000, being 2.4 below that for the previous quarter, and 0.1 below the standard figure for this period in the preceding five years. In the aggregate of large burghs the death rate was 10.9 as compared with 10.8 for the rest of Scotland. Deaths registered during the three months under review were: for July, 4,512; for August, 4,303; and for September, 4,427; with equivalent monthly death rates of 11.0, 10.5, and 11.1 respectively. As regards infant mortality, the deaths of children under 1 year numbered 1,353, equivalent to a death rate of 60 per 1,000 registered live births. This number was 514 less than in the previous quarter, while the rate compared favourably with the standard rate of 64 per 1,000 for this quarter. The rate in the aggregate of large burghs was 65 as compared with 53 for the rest of Scotland, the rate ranging from 83 in Perth, 76 in Ayr and Stirling, and 73 in Glasgow, down to 33 in Dumfries and Hamilton, and 10 in Dumbarton. In the counties the rate ranged from 100 in Kinross, 98 in Caithness, down to 17 in Bute, 20 in Peebles, and 0 in Sutherland. Of these deaths 3.6 per cent. were attributed to the principal epidemic diseases, including 97 from measles, 19 from scarlet fever, 121 from whooping-cough, 69 from diphtheria, 56 from influenza, and 54 from cerebro-spinal fever. The main feature in this group, as compared with the previous quarter, was the diminution of the deaths attributable to each of these diseases, with the exception of measles, from which 13 more deaths were recorded. Deaths from all forms of tuberculosis accounted for 7 per cent. of the total number. The quarterly death rate from all forms of tuberculosis was 76 per 100,000 as compared with the standard rate of 83, and from respiratory tuberculosis 54 as compared with 58. Malignant disease accounted for 13.3 per cent. of deaths from all causes; although this represents 42 more than in the previous quarter, the rate is exactly equal to the standard for the same quarters of the previous five years. Deaths of mothers from diseases and accidents of pregnancy and childbirth numbered 115, equivalent to a rate of 508 per 100,000 births, which is 124 per 100,000 below the standard average for the past five years. The total number of deaths assigned to accidents with motor vehicles was 201, or 48 more than those recorded in the previous quarter.

Sanitary Progress in Edinburgh

At a general meeting of members of the Edinburgh Women Citizens' Association, held on December 3rd, Mr. Allan W. Ritchie, chief sanitary inspector for Edinburgh, gave an account of recent sanitary progress in the city. He said that Edinburgh used to have a reputation for extreme congestion, dingy and foul dwellings, and absence of sanitary facilities. Much had now been done by the city council for cleanliness, health, and the well-being of the community, but a great deal could still be done to secure a cleanly and healthy environment for the whole mass of citizens. In the larger question of housing and sanitary reform the corporation was carrying out various slum clearance schemes. A great transformation had taken place in the lives of occupiers transferred to new homes in the districts of Lochend, Prestonfield, and Niddrie. It had been found that a few tenants lagged behind in the progress of improvement, but, generally speaking, the change wrought by the majority of the transferred inhabitants had been remarkable. There were still many families throughout the city living in overcrowded conditions, but these were receiving attention as alternative accommodation became available. There were numerous instances of sub-letting in small two-apartment houses, where all the accommodation was intended for one family. It was found that the charges for sub-letting rooms sometimes exceeded the normal rent of the whole house, and this form of overcrowding was a very serious matter, which resulted in cramping of sleeping accommodation and lack of separate accommodation for the different sexes. With regard to smoke abatement, much had been done by approved methods in firing factory furnaces and heating public buildings, as well as by the extended use of gas and electricity in houses; the demand for solid smokeless fuel was gradually being met. With regard to clean food production, many places where food was produced had now been modernized, and there had been a widespread adoption of the practice of making up foodstuffs in packets and wrappings to lessen the amount of handling. Great strides had also been made in the better distribution of milk, which was now largely delivered in sterilized bottles.

Child Guidance Clinic

A child guidance clinic for Roman Catholic children has been established, with the approval of the ecclesiastical authorities, at India Buildings, Edinburgh. This is intended to deal with "problem" children who, with average home conditions, discipline, and physical care, fail to conform in behaviour to average children of similar

with this or that food substance. The laborious and complicated nature of the work would, however, seem to make it difficult to do adequate controls, and would give an opening for accidental results. I find myself, in reading of them, saying, "I wonder if he did this control!"; "I wonder if he had any results going the wrong way!" I hesitate to write that comment because it seems a niggardly recognition of a great deal of very ingenious work. Five years ago Dr. D. Morien Thomas and I attempted to sensitize passively thirty guinea-pigs, most of them with serum from hay-fever patients, but some with serum from horse-asthma cases. We tried a variety of methods, but did not succeed in sensitizing any one of the guinea-pigs to pollen or to horse dandruff, as judged either by dermal reactions or by Dale's uterus technique.

With regard to Dr. Barber's clinical evidence, it is always difficult to ascribe with certainty a "reaction" to this or that inoculation dose, and never more so than in patients of the asthma type. I have got such dramatic "reactions" after control injections of normal saline that I distrust such clinical evidence. Dr. Barber's warning that it may be dangerous to use more than a fortieth of a cubic centimetre of a hundred-million-fold dilution of "proteose" gives me a shock when I reflect that I injected a twentieth of a cubic centimetre of what I believe was the undiluted "proteose" prepared by Dr. Oriel and got absolutely no effect with it, either local or general. If we accept Dr. Barber's clinical evidence, then the fact that reactions occur usually on the third day after his dose again suggests very strongly that this business is not comparable to, say, horse asthma or egg sensitiveness.

Turning now to Dr. Oriel's letter in your last issue, it is interesting to learn that the "protcose" made by him, which had failed to react intradermally on my asthmatic eczema patient who had produced it, was subsequently used to make a guinea-pig typically anaphylactic; this shows that, whether or not it reacted specifically on my patient, it was at any rate capable of functioning as an antigen.

The difficulties stated in my original letter have not been, for me at least, removed. I think we may say that the "proteose" reactions do *not* stand on the same footing as, for instance, the pollen dermal reactions for hay fever. Though the work on the "protcoses" is interesting and suggestive, I would regard their character as still *sub judice*.—I am, etc.,

JOHN FREEMAN.

London, W., Dec. 12th.

RICKETS AND GROWTH OF BONE

SIR,—Rickets is unfortunately still too prevalent both in London, in the provinces, and in the countryside, and is even found quite commonly among the children attending infant welfare centres.

It is notorious, too, that some of the children are much deformed. While I agree with Dr. Thursfield that the gross deformity due to rickets is seen less frequently, it is my own experience to come across daily deformities of less severity, but still requiring instrumental or operative correction. Further, they occur from time to time in children who, it is alleged, have been fed in accordance with instructions from their medical practitioner or from the doctor in charge of the infant welfare centre. They also arise, alas! in the children of well-to-do parents, who have been nursed, it is alleged, with their mothers' milk in the normal way.

It would therefore appear that there is still much to be done to eradicate rickets and its deformities.—I am, etc.,

B. WHITCHURCH HOWELL, F.R.C.S.

London, W. 1, Dec. 1st.

DEATHS ASSOCIATED WITH ANAESTHESIA

SIR,—It appears to me that this question requires a good deal of ventilation. Dr. W. Howard Jones, in the *Journal* of December 5th, makes some very pertinent remarks—for example, that "Dr. Hoffman must prove to our satisfaction that their [the American] system of registration is as stringent throughout the States as it is in this country before any value can be given to his figures." I imagine that in this country, if anyone dies of advanced disease of any sort, provided he dies under an anaesthetic, this death is classified as due to anaesthesia—a grossly unfair classification.

But apart from systems of registration it is quite probable that there are too many "anaesthetic deaths" here as compared with the United States of America—this, in spite of the fact that in the States, as we are told, nurses, not doctors, administer large numbers of anaesthetics. This raises another point—namely, that the administration of anaesthetics, although based on scientific principles, is to a very great extent what might be called an art rather than a science, so that it is likely that if any nurse is chosen to give anaesthetics after an adequate training, and devotes her whole attention to this branch of her work, then her results may average out better than those of the (comparatively) untrained general practitioner or house-surgeon who is frequently called upon to administer anaesthetics in this country. Again, the most important point of all, large numbers of anaesthetics are given in this country, so to speak, casually—for example, in the dentist's surgery or at the patient's house, with no adequate preparation, and by practitioners who may perhaps not be giving more than half a dozen anaesthetics in the course of twelve months.

It is perhaps to some extent our own fault that the public does not realize the importance of a properly qualified anaesthetist, and therefore will not pay his fee as well as that of a competent surgeon. The surgeons themselves realize the importance of the anaesthetist. In the bigger towns, at least, one seldom finds a surgeon operating without the help of his own anaesthetist, and it would be interesting to know what proportion of the anaesthetic deaths occur when the surgeon who is operating has the assistance of the anaesthetist whom he habitually employs.

Mr. Ernest H. Griffin's criticism appears at first sight somewhat ill informed; no anaesthetist is likely to spend £200 to £300 on apparatus which he is not competent to handle. At the same time, the point he makes is very important—namely, that in giving anaesthetics, as in all other "games of skill," it is vital "to keep your eye on the ball."—I am, etc.,

R. K. ROBERTSON,
Anaesthetist, Sheffield Royal Hospital

December 9th.

SIR,—Dr. Howard Jones's letter (December 5th) does explain, in a sentence, the real reason for the difference in the British and American figures. He says: "But we are aware that the conditions in America are very superior to those prevailing here." On page 10 of *Anaesthesia* (Blomfield) we find this, which puts the matter in a nutshell.

"Thus the Gordian knot of chloroform danger has been untied by cutting it. If anaesthetists have not succeeded in robbing chloroform of its perils, at any rate they have learned to get good results without it. Much of this progress has been due to American work. From that country came the ideal of shockless operation, and the practice of complete local and general anaesthesia as founded by Crile upon physiological experiments. American physiologists and anaesthetists have expended trouble and imagination in devising numerous forms of apparatus for the smooth and precise administration of nitrous oxide and in exploring the physiology of the anaesthesia obtained. Their efforts have met with much success."

Dr Howard Jones's faith in the accuracy of the British figures one can admire, but, knowing something of the real conditions, one feels it is slightly misplaced Probably the American figures are not correct either, but having seen anaesthetics given in the United States and Canada, my surprise is that the figures are so much in our favour I do not know the figures for the Mayo Clinic, for instance, but if accurate records are kept anywhere I should imagine it is there Those, at any rate, can be obtained I saw some anaesthetics given in Crile's Clinic at Cleveland, and spoke to the patients, their post operative condition was wonderfully good, and if his post operative death rate is not very low indeed I shall be greatly astonished At the Presbyterian Hospital in Chicago, when I was there about four years ago, *10,000* anaesthetics of ethylene and oxygen had been given, with no death in any way attributable to anaesthesia

I agree with Dr Howard Jones that sometimes, in this country, deaths are attributed to anaesthetics which should truly be put down to another cause Certainly the figures should be either disproved or explained To me the explanation is clear It is summed up in their more accurate methods, the use of precise instruments, lighter anaesthesia, and less rule of thumb, and generally a much more thorough investigation of the pre operative condition of surgical patients Until we do as much we cannot hope to approach the American figures —I am, etc,

E J CHAMBERS, M R C S, L R C P

Doncaster, Dec 6th

SIR,—As Dr Hoffman's letter in your issue of November 28th simply begged for contradiction, I felt certain that dozens, better qualified than I to speak, would hasten to point out the obvious fallacy in his comparison To-day I am disappointed to find that, though Dr Howard Jones ably and tactfully indicates certain probabilities of error, no one has troubled to note that Dr Hoffman's conclusion is based on a false premise Please allow me to repair the omission by asking a question How can the number of deaths associated with anaesthesia, when *expressed as a rate per 100,000 population*, pretend to reflect the actual state of affairs?

Emergency operations are responsible for by far the greatest number of such deaths, and the splendid hospital system of America contributes (in those densely populated districts to which its splendour is confined) to the low death rate more by ease of access than by any superiority in anaesthetic methods On the other hand, there are vast tracts of the United States that are beyond what one might call the "acute" radius of an operating theatre, so their statistics are further diluted by the not inconsiderable number of people who die from acute conditions before they get as far as a hospital or an anaesthetic In Great Britain the hospital system may lack some of the American efficiency, but the institutions are so freely scattered throughout the land that it may be said that no one is so far from a suitable hospital that he may not at least reach the operating table before he succumbs

Surely the only basis for such a comparison as Dr Hoffman desires to make is the number of deaths *expressed as a percentage of anaesthetics administered* And even then, numerous restrictions would require to be applied in compiling statistics, as for example (1) All deaths under anaesthesia, as in this country, must be recorded as such, even if obviously and indubitably due to the patient's disease (2) The type of operation associated with each death must be indicated There can be no comparison between, for example, an operation for toxic goitre, on the one hand, and for a chronic appendix, on the other (3) Local, and, particularly, peripheral anaesthesia, must be expressly included or excluded in compiling *both* lists of anaesthetics administered (4) We must feel reasonably certain that all surgeons are as completely uninfluenced by what Dr Howard Jones so aptly calls "enthusiasm for results" as are our surgeons, that every patient who stands the slightest chance of being saved will be given that chance—as he is here—even though the surgeon is aware that he is almost certainly adding one more to his personal list of "deaths on the table"—I am, etc,

Edinburgh, Dec 5th E J THOMSON

ETHER CONVULSIONS

SIR,—I have read with interest the reports of cases of ether convulsions which have appeared recently, and I should like to record my own experience

The patient a boy of 12 years was admitted under Mr C A Joll on November 23rd with severe lacerations of the left leg and thigh I gave him open ether while the leg was cleansed and an attempt made to repair the damaged tissues in the hope of saving the leg The operation and the post anaesthetic phase were uneventful Twenty-four hours later gangrene of the skin had set in so amputation was carried out at once I again gave open ether, and towards the end of the operation convulsions set in The first sign was a twitch of the neck muscles, but as the femur was being sawn through at the moment, and one arm was being prepared for an intravenous saline, necessitating some movement of the patient I was not convinced that it was a genuine twitch A few seconds later pronounced twitching of the neck muscles began and I at once stopped the anaesthetic The twitching spread rapidly to the face and then to the body and limbs and lasted fifteen minutes During a short part of this time there was slight cyanosis and I gave oxygen, but for the greater part of the time the colour was good The pulse was rapid (130) but regular and of good volume considering the general condition The twitching ceased in the reverse order to which it had begun the legs first then the body the face a few moments later and the neck last of all Up to the present the boy is improving steadily

This is the third case I have experienced the other two being of a similar type—that is, children with gangrenous appendices, who both made uninterrupted recoveries It would appear from these cases that the septic element is very much to blame —I am, etc,

PHYLLIS F L SIMON,
Anaesthetic Registrar, Royal Free Hospital

December 4th

RITTER'S DISEASE

SIR,—Dermatitis exfoliativa neonatorum is undoubtedly (and fortunately) rare, but it is not entirely unknown in this country Dr MacKay (*British Medical Journal*, December 5th) will be interested to hear that two typical cases have in past years come under my care in the Royal Liverpool Children's Hospital Both of them died In addition, I have seen in consultation a more doubtful case, which recovered In this the diagnosis lay between mild von Ritter's disease and severe pemphigus neonatorum (bullous impetigo)—if, indeed, there be any essential difference between the two diseases except the severity of the symptoms and the consequent prognosis —I am etc,

Liverpool, Dec 8th HUBERT ARMSTRONG

END RESULTS OF CHOLECYSTECTOMY

SIR,—Cholecystectomy has now been practised for many years We are familiar with the excellent immediate results but what are the end results? Is there anywhere available a record of the pathological conditions found at necropsy or of the state of the bile duct discovered in subsequent operations whether for recurrent cholelithiasis or for other complication? What happens? Does the common bile duct become dilated and its form?

Does this dilatation extend upwards? Is an infected condition of the bile apt to continue or to supervene, with a tendency to toxic absorption or to recurrent formation of gall-stones?

Can any of your readers throw light upon these matters? There should by now be a store of accumulated experience if it were only made available.—I am, etc.,

ERNEST F. NEVE, M.D.

London, Dec. 4th.

NEO-HIPPOCRATISM

SIR,—The letter from Dr. Warden of Cannes in the *Journal* of November 28th must appeal to all students of the history of our profession. Dr. Warden expresses what many of us are thinking to-day about our healing art in relation to the world changes around us. We feel that it would be regrettable and, in any historical perspective, disastrous if we should leave entirely to lay enthusiasm the task and also the glory of reducing our confused therapeutics to Hellenic simplicity. This matter is in many minds to-day. Following Dr. Hutchison's masterly statement I anticipate a lively discussion of this tremendous subject by those more competent than myself to handle it.

To what Dr. Warden has said I wish only to add a note about the Sunbathing Society in London. Readers of the *Journal* need not go to Germany to inspect the latest form of therapeutics. The Sunbathing Society, founded at Norwood by a layman, has shown itself always most anxious to co-operate with the medical profession. No attempt is made to treat specific ailments until the family doctor has first been consulted. About two years ago I referred to this society in a letter in your columns about active sun- and air-bathing. Subsequently many practitioners wrote expressing interest, and several joined the society. There is to-day universal interest in sun and air and water as healers. Even the daily newspapers, for so long unable to decide whether sun-bathing was buffoonery or lechery, have joined the chorus of sun worshippers.

With the approval of the mayor and corporation of Croydon the Sunbathing Society now has four acres of woodland on the hills at Addington. Here, remote from London smoke, contact may be made with the above-mentioned simple therapeutic agents. In a sympathetic notice of *Man and Sunlight* by Hans Suren your reviewer asked how his recommendations could be adopted on any appreciable scale in this country. That was in 1928. In 1931 the activities of the Sunbathing Society provide an answer.—I am, etc.,

REGINALD HODDER, M.R.C.S., L.R.C.P.

Penge, Nov 29th.

"BUY BRITISH"

SIR,—The recent inauguration of the "Buy British" campaign by H.R.H. the Prince of Wales calls from our profession as a whole for much more than passing approval.

Brief reflection on the material used in daily practice, such as catgut, rubber gloves, instruments, proprietary medicines, toilet requisites, plaster-of-Paris bandages, electric lights, sterilizing equipment, and *x*-ray material, causes a somewhat startling realization of the extensive sums which leave this country in payment for these foreign goods. Further investigation would probably extend this list considerably, but it is convincing enough to prove the scope for the use of British goods in practice and in hospital. A well-deserved stimulus would be given to our established industry and enterprise, and foreigners would be encouraged to manufacture in this country.

Recently a firm of foreign wholesale druggists opened a factory in England. This was cheering from many points of view, but less pleasant was the revelation from one of the directors that he had no difficulty in obtaining trained research chemists with honours degrees for a salary of £180 to £200 a year, which is considerably less than he paid his shorthand-typists. By insisting on the "Buy British" slogan, the deplorable depreciation in the value of our own finer intellects will be lessened, and a splendid opportunity will be available for our professional hospital boards of management, and public health authorities, etc., to help Britain towards a greater independence and prosperity.—I am, etc.,

HAROLD DODD.

London, W.1, Dec. 3rd.

TUBERCULOSIS RESEARCH

SIR,—I am engaged in investigating the bacteriology of the tubercle bacilli to be isolated from the sputum in cases of pulmonary tuberculosis in which there is a definite history or other clinical evidence of a *previous* glandular infection. Such cases are not common, and I venture to beg the courtesy of your correspondence columns in order that I may ask if any tuberculous officers, sanatorium superintendents, or others who have such cases under their care, would be good enough to let me have specimens of sputum. It is not essential that tubercle bacilli be demonstrable microscopically, so long as the lung lesion is tuberculous. If anyone will send me a post-card I shall be very glad to send suitable container, cover, etc.—I am, etc.,

W. M. CUMMING

Bradford City Sanatorium, Grassington, Yorkshire, Dec. 6th.

Obituary

C. A. LEEDHAM-GREEN, CH.M., F.R.C.S.

Consulting Surgeon, Queen's Hospital, Birmingham

Mr. Charles Albert Leedham-Green, who died recently at Trevone, Cornwall, was at one time a prominent figure in the medical world of Birmingham. He was born in 1867, and was educated at Queen's College, Birmingham, where he won the Ingleby Scholarship, and at the Universities of Göttingen and Heidelberg. He obtained the M.R.C.S. and L.R.C.P. diplomas in 1891, and became a Fellow of the Royal College of Surgeons of England in 1893, in which year he graduated M.D. of Heidelberg. Before settling down to surgical practice in Birmingham he had been demonstrator in physiology and assistant lecturer in bacteriology at Mason College, Birmingham, and assistant surgeon in the University Surgical Clinic at Göttingen. He became surgeon to out-patients at the Queen's Hospital, Birmingham, in 1897, and was promoted full surgeon nine years later. On retiring from the active staff in 1921 he was elected consulting surgeon. He was also, for some years, consulting surgeon to the Birmingham Dispensary, the Redditch Hospital, and the Tamworth Hospital; surgeon to the Birmingham Hospital for Sick Children; and joint professor of surgery in the University of Birmingham, in which he had graduated M.B. soon after its incorporation by Royal Charter in 1900, and Ch.M. three years later. During his professional life Mr. Leedham-Green contributed a number of papers on surgical subjects to British and German periodicals. He published a small work on *Stenhouse's Hands* in 1896, and his book on the *Treatment of Gonorrhoea in the Male* reached a third edition. When the British Medical Association held its Annual Meeting at Birmingham in 1911, under the presidency of Sir Robert Saundby, he acted as joint secretary of the Section of Surgery.

As may be judged from the brief outline of his career printed above, Mr. Leedham-Green was a surgeon highly esteemed in Birmingham and the Midlands. He was

and forceful personality inspired confidence, and he was full of enterprise and resource in all operative procedures Nevertheless, though stimulating to the individual dresser and house surgeon, he found it difficult to make effective contact with students in the mass during the routine work of a lecturer on the principles and practice of surgery

We much regret to announce that Dr MARK HENRY HERBERT VERNON died at his residence at Horsham, Sussex, on December 7th, aged 78 He was educated at Marlborough College and at St Bartholomew's Hospital, where he later held the appointment of ophthalmic house surgeon In 1875 he won the Brackenbury scholarship and took the M R C S diploma, and in the following year the L R C P After being resident surgeon to Leeds General Infirmary he went to Horsham in 1878, as a member of the partnership Bostock, Bostock and Vernon, and practised there until 1922, when he retired On several occasions Dr Vernon was chairman of the Horsham Division of the British Medical Association, and was elected president of the Sussex Branch in 1926 and again in 1931 After his retirement he gave much time to public affairs, being chairman of the Horsham Urban District Council, and a member of the West Sussex County Council The funeral took place on December 10th at Horsham Parish Church Dr L A Parry writes We of the Sussex Branch have sustained a great loss by the death of our president, Vernon of Horsham He has been one of us for so long, helping us by his sound advice and by his kindly and courteous dealings with us, that we have come to look on him as one of the elders on whom we could always rely for assistance I have had the privilege of serving as secretary of the Branch both during his first presidency in 1926 and during his present term of office, and I have been able to go to him at any time when needing help with the full assurance that he would give me all of which he was capable His loss to me, and I know to all of us in the county, is great We shall remember him as a true friend and as a doctor of the very best type, always willing to give of his large knowledge of men and affairs to those of us who consulted him *Requiescat in pace*

Dr LOUIS BENNETT CLAREMONT, who died on November 23rd, at the age of 71, received his medical education at University College Hospital, where he obtained the diplomas M R C S, L R C P in 1882, and was obstetric assistant to the late Sir John Williams He then joined his father in practice in Hampstead Road, N W, for twelve years, after which he removed to Haverstock Hill, and subsequently to Golder's Green Dr Claremont held several public appointments in St Pancras and Highgate, including those of public vaccinator for St Pancras and medical officer to the St Martin in the Fields Almshouses, both of which posts he took over from his father He was also nose, throat, and ear surgeon to the St Pancras Clinic, Kentish Town, and to the Highgate New Town Clinic, in the construction and equipping of which he had been active Dr Claremont was a member of the British Medical Association During the war he acted as clinical assistant at the Golden Square Throat Hospital, in order to release younger medical men for active service His son, Dr Edmund Claremont, is director of the Eastman Dental Clinic at the Royal Free Hospital

Dr DONALD STEWART DEWAR of North Shields, who died on December 10th, after a short illness, was born in 1871, and graduated M B, C M, at the University of Glasgow in 1894 After practising successively at Ronaldkirk, Yorkshire, and Whitley Bay and Willington Quay, Northumberland, Dr Dewar went to North Shields in 1925 The honorary secretary of the Tyneside Division of the British Medical Association, of which Dr Dewar was a member, writes Whilst of a retiring disposition he had a most genial and engaging personality, which endeared him to his patients and made a lasting impression upon all his colleagues He possessed a high sense of duty and honour, and his cheerful and unassuming personality will be missed and remembered by all his many lay and medical friends Dr Dewar leaves a widow, one son, and one daughter.

The following well-known foreign medical men have recently died Dr ANTONIO DIONISI, professor of morbid anatomy at the University of Rome, Dr JOHN BLAIR DEAVER, professor of surgery at Philadelphia, and author of works on surgical anatomy, appendicitis, disease of the breast, and enlargement of the prostate, aged 76, and Dr APCILE ZAMORA, professor of therapeutics in Bolivia

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

Both Houses of Parliament stand adjourned till February 2nd, but the Lord Chancellor and Speaker are authorized to summon them earlier if emergency requires this

Before the House rose on December 11th the Royal Assent was given to the Horticultural Products (Emergency Duties) Act, the National Health Insurance (Prolongation of Insurance) Act, and the Statute of Westminster Act On the same day, in the House of Commons, Major Oliver Stanley, Under Secretary for Home Affairs, presented the Children and Young Persons Bill, "to make further and better provision for the protection and welfare of the young and the treatment of young offenders, to amend the Children Act, 1908, and other enactments relating to the young and for objects connected with the purposes aforesaid" The second reading of this Bill is put down for February 4th The business for February 2nd is the second reading of the Town and Country Planning Bill

India and Medicine

During the debate on Indian policy in the House of Commons on December 2nd Dr W J O'Donovan spoke of the service which European doctors had rendered to Indians. Without distinction of colour race or political outlook, England and Western civilization had given India the boon of life Malaria reduced fertile plains to wild jungle, and made man unable to contest with nature In the medicine taught in the schools of Europe India saw a prospect of being freed from that scourge Hookworm disease, which made men unfit to work, afflicted 60 to 70 per cent of the population in some parts of India It had been studied in British and Continental schools of medicine but to that study his Indian colleagues had contributed practically nothing In the Section of Tropical Diseases of the Royal Society of Medicine, and in the Hospital for Tropical Diseases in Endsleigh Gardens, London, the dysenteries were studied, and the benefit of that research was at the disposal of every Indian hospital Were English medicine and the English connexion to be abruptly cut off, Indians would suffer Similarly with leprosy if modern medicine and research were allowed full play leprosy could be abolished The history of Indian medicine was empty of any records of the study and cure of cholera Many of his professional brothers had died because of that disease and its investigation and it was sad that in the Government's White Paper on India and the records of the *Round Table Conference* the work of the medical profession was almost unrecorded Tuberculosis was as prevalent in India as in the United Kingdom perhaps because of that custom of enclosing their womankind which led to stunted growth, early death and death in childbirth That custom could only be broken by a great increase in medical education throughout the Indian Empire He drew attention to the keenness of Indian students to study in England Deans of medical schools were hard put to it to find places for them This proved that England had much to give to India and that politicians should do nothing until a precedent that help being freely offered He had never been in India but so intimate was the knowledge of the London medical schools had of the medical needs of India that he spoke

as one to whom these things were an everyday matter. Politics were phantoms unless addressed to the health of the people, which was more important than votes or status.

Mr. E. T. CAMPBELL, as one who had lived twenty-one years in the Tropics, congratulated Dr. O'Donovan on his interesting speech.

Miss ELEANOR RATHBONE adduced evidence that the average life of an Indian was 25 years, as against 54 for an Englishman, and that the Indian death rate was 30 to 35 per 1,000. Even in the large towns few sick people ever saw a doctor, and certificates of death were usually guesswork by a non-medical registrar. Abject poverty and ill-health were the cause of Indian discontent, and she trusted that the committees of inquiry which the Government proposed to set up would make possible a quickening of the slow pace of Indian social reform in health, and, above all, in the conditions of marriage and maternity.

Sir SAMUEL HOARE, Secretary of State for India, congratulated Dr. O'Donovan on his useful contribution to the debate.

Shop Hours: Sale of Medicines, etc.—Sir HERBERT SAMUEL, in reply to Mr. Goldie on December 10th, stated that shops were required by the Shops Act, 1912, to close for a weekly half-holiday, but an exemption was provided for the sale of medicines and medical and surgical appliances. Though there had been no legal decision, chemists in Central London treated toothbrushes as covered by this exemption. Wherever there was legislation dealing with such a matter as a weekly half-holiday for shops, some special exceptions must be permitted. Any amending legislation would involve either the surrender of the half-holiday or else borderline cases of a different character.

Asbestosis.—In reply to Mr. J. Jones, on December 10th, Sir HERBERT SAMUEL said 582 workers engaged in the asbestos industry had so far been examined by members of the medical board; three had been found to be suffering from asbestosis, of whom one had been certified to be totally disabled, and two had been suspended. In addition, one had been suspended on account of tuberculosis and one on account of defective physique, making a total of four who had been suspended. In seventy-seven of the cases examined the Board was awaiting the result of a radiological examination, and had come to no conclusion. Replying to Dr. Fremantle, he said these figures covered the period since June, when the measure came into force.

Mental Hospital Accommodation.—Sir E. HILTON YOUNG told Dr. J. H. Williams, on December 10th, that the initial cost of providing a bed in a mental hospital might be estimated at £500 at present, but the annual cost of maintaining it was about £70. The suggestion that expense might be avoided by the provision of suitable and inexpensive hostels for slight and temporary cases that did not require detention was impracticable, because the adequate preventive treatment of incipient cases required resources of staff and equipment which could not be provided in inexpensive hostels.

Imported Fruit Pulp.—Replying, on December 10th, to Mr. Dunner, Sir E. HILTON YOUNG said imported fruit pulp was examined at the ports under the Imported Food Regulations, which empowered the sanitary authorities to seize for destruction any articles of food which were found to be diseased, unsound, unwholesome, or unfit for human consumption. At present there was no information which would justify the prohibition of the importation of Russian fruit pulp in the interests of public health.

Veterinary Research.—Replying on December 10th to Dr. Fremantle, Sir J. GILMOUR said the Ministry of Agriculture had formulated proposals for the development and co-ordination of veterinary medical research. These were now under discussion with the Agricultural Research Council. Any scheme finally settled could only be put into operation as and when financial circumstances permitted.

B.C.G. Vaccine.—Sir HERBERT SAMUEL told Sir F. Sanderson, on December 10th, that a licence under the Cruelty to Animals Act, accompanied by Certificate A, would permit experiments upon animals with the Calmette or B.C.G. vaccine to be conducted. Some research work on the subject had been done in this country.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

The Faculty Board of Medicine has appointed the following to be members of the Committee for Medical Radiology and Electrology for the year 1932: Professor J. T. Wilson, Dr. G. S. Graham-Smith, Dr. Stanley Melville, Dr. E. P. Cumberbatch, Professor Sidney Russ, and Dr. Russell J. Reynolds.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

A meeting of the Council of the College was held on December 10th, with Lord Moynihan, the President, in the chair.

Court of Examiners

Mr. E. Rock Carling (surgeon to the Westminster Hospital), Mr. A. E. Webb-Johnson (surgeon to the Middlesex Hospital), and Mr. Claude H. S. Frankau (surgeon to St. George's Hospital) were re-elected members of the Court of Examiners.

Diplomas and Licences.

The Fellowship of the College was conferred on the following forty-six candidates:

H. E. Harris, C. S. Hallpike, E. Jacobson, Diana J. K. Beck, Gertrude M. B. Morgan, C. L. Owen, O. Hooper, E. S. Evans, J. K. Monro, H. E. James, A. B. Pain, R. W. Raven, A. H. S. Handousa, G. S. Storrs, J. C. F. L. Williamson, T. H. Bevill, E. C. B. Butler, J. B. Blaikley, B. W. Rycroft, S. N. Mather, A. M. Boyd, V. Hariharan, A. S. Philps, N. C. Tanner, Ebra Hargreaves, T. H. Wilson, P. V. Reading, P. B. Ascroft, Margaret M. White, H. A. Phillips, H. G. Letcher, D. S. P. Wilson, H. L. Body, D. D. Boovariwala, S. B. Cooper, A. Cruickshank, R. Lal, D. M. Mitchell, D. H. Mitchell, L. M. Park, E. E. Price, L. S. Rogers, T. O. Sayle, H. H. Skeoch, V. S. Stone, F. Welsh.

A diploma of Membership was granted to E. A. Knappett, and the Licence in Dental Surgery was conferred upon fifty-six candidates.

Appointments

Sir John Rose Bradford, Bt., was elected a member of the Executive Committee of the Imperial Cancer Research Fund, on the nomination of the General Committee of the Fund.

It was reported that the Secretary of State had appointed Mr. W. Sampson Handley to be a member of the Advisory Committee on the Administration of the Cruelty to Animals Act, 1876, in place of Sir Charters Symonds.

Legacy

It was reported that a legacy of £50, free of duty, for the laboratory fund of the College, had been bequeathed by the late Dr. F. W. Collingwood.

Representation of Members on the Council

The Council considered the following resolution, which was carried at the annual meeting of Fellows and Members on November 19th:

That this forty-third annual meeting of Fellows and Members of the Royal College of Surgeons reaffirms that it is essential that Members, who constitute nine-tenths of the College, should be admitted to direct representation on the Council, especially having regard to the striking result of the poll of Members taken last year.

The following reply to the resolution was adopted:

The Council, having considered the report of the proceedings at the annual meeting of Fellows and Members, adheres to the opinion expressed at its meeting in January, 1931.

Primary Fellowship Examination

The following 53 candidates, out of 180 who presented themselves, were approved at the examination held from December 1st to 12th:

S. W. Allinson, A. W. Badenoch, G. T. Balean, H. C. Evans, J. Bastow, G. H. Bateman, R. H. R. Belsey, M. J. Bennett, J. G. Bowen, V. R. Clifton, R. B. W. A. Cole, A. L. Dallas, R. P. Dalal, R. S. de Bruyn, Jean M. Dillar, C. L. S. Dodd, R. S. Ellis-Brown, F. I. Evans, W. J. Ferguson, J. D. Fergusson, E. O'D. C. Grattan, A. Hilmy, J. E. Hughes, A. T. Hunter, D. W. Jones, L. E. Jones, B. L. Kapur, A. McDowall, D. B. Mc[illegible], A. H. McIndoe, Jocelyn A. M. Moore, R. F. Mould, J. H. Moynihan, C. S. Patel, P. H. L. Playfair, D. C. Price, J. Robertson, M. A. Robertson, I. G. Robin, Enid H. Rose, J. R. Rose, B. J. Sanger, N. T. H. Schafer, G. M. A. Scott, T. G. Tregaskis, R. W. D. Turner, F. H. Weston, C. W. Willard, S. L. Wilson.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW

The following have been admitted Fellows of the College: David Riddell Campbell, Malcolm Carfrae Douglas, John Dunn, Gilbert Garrey, James Livingstone Loudon, Alexander Miller, Ellen Brown Orr, Albert Arthur Fitzgerald Peel.

Medical News

The house and library of the Royal Society of Medicine will be closed from Wednesday, December 23rd, to Saturday, December 26th, both days inclusive.

The Institute of Medical Psychology, 51, Tavistock Square, W.C.1, has arranged a series of twenty lectures on psychological types and mechanisms as an introductory course in psychological medicine for the general practitioner. It will be given at the Friends House, Euston Road, N.W.1, on Wednesdays, beginning January 20th, 1932. The course is divided into two series, ten lectures being given by Dr. E. Graham Howe and ten by Dr. H. Crichton-Miller. The fee for either series is £1 11s. 6d., or for both series £2 2s.

A three months' course of lectures and demonstrations on clinical practice and in hospital administration for the D.P.H. (instruction in hospital administration) will be given at the Brook Hospital, Shooters Hill, S.E.18, by the medical superintendent, Dr. J. B. Byles, on Tuesdays and Fridays at 3 p.m., and alternate Saturdays at 11 a.m., beginning on Tuesday, January 5th, 1932. Medical men proposing to join the course must, before attending the hospital, pay the fee, £3 13s. 6d., to the Medical Officer of Health, London County Council, Public Health Department (Special Hospitals), Victoria Embankment, E.C.4.

The Fellowship of Medicine and Post-Graduate Medical Association announces a course of lectures on treatment, to be given at the Medical Society of London, 11, Chandos Street, Cavendish Square, on Wednesdays, at 4 p.m., from January 13th, 1932. These lectures are free to members of the Fellowship; the fee to non-members is £1 1s. for the series of nine, or 5s. a lecture, payable at the lecture room. An evening course of six lectures on endocrinology will be given by Dr. Langdon Brown at the Medical Society of London on Mondays and Fridays at 8.30 o'clock, starting January 11th; fee for the series £3 3s., or 12s. 6d. a lecture, payable at the lecture room. In future, all special courses and lectures arranged by the Fellowship of Medicine will be open only to its members; the annual subscription is £1 1s., including the monthly *Post-Graduate Medical Journal*. A lecture-demonstration on rheumatic infection and heart disease in children will be given by Dr. Bernard Schlesinger at the Children's Heart Hospital, West Wickham, Kent, on Saturday, January 2nd, from 10.30 a.m. to 12 noon; fee 7s. 6d., payable to the Fellowship, 1, Wimpole Street, W.1; applications must be received by December 28th.

At the December meeting of the Central Midwives Board for England and Wales the dates of the ordinary meetings of the Board for the year 1932 were fixed as follows: January 7th, February 4th, March 3rd, April 7th, May 5th, June 9th, July 21st, October 6th, November 3rd, and December 1st.

The twenty-second annual exhibition of scientific instruments and apparatus, arranged by the Physical and Optical Societies, will be held on January 5th, 6th, and 7th, 1932, at the Imperial College of Science and Technology, South Kensington, from 3 to 6 p.m., and from 7 to 10 p.m. Tickets may be obtained from the exhibition secretary, Institute of Physics, 1, Lowther Gardens, Exhibition Road, S.W.7. Admission on January 7th will be free, without ticket.

The presidential address of the West London Medico-Chirurgical Society, on the relationship of the general practitioner to the voluntary hospitals, is published in full in the fourth quarterly number of the *West London Medical Journal*.

A special matinee was arranged by Mrs. Frank Worthington at the Aldwych Theatre, on December 10th, in aid of the Royal Free Hospital, and the East London Hospital for Children, Shadwell. The play, *The Black Parrot*, by H. Fletcher Lee, was admirably produced by Mr. Wilfred Fletcher, who also gave an excellent rendering of Philip Quinton, the husband of Lois Quinton, the leading lady, whose part was played with great charm by Mrs. Frank Worthington herself. The matinee was a brilliant success, and the Royal Free Hospital and the East London Hospital for Children have every reason to be grateful to Mrs. Worthington and all who helped her, as we understand that by this and another performance of the same play she has raised £960 for these two charities.

The *Deutsche Zeitschrift für Chirurgie* and the *Zentralblatt für Chirurgie* have each published a Festschrift on the occasion of Professor August Bier's seventieth birthday, which was celebrated at the Langenbeck-Virchow House on November 23rd.

The next annual congress of the Royal Institute of Public Health will be held in the city of Belfast from May 10th to 15th, 1932, on the invitation of the Lord Mayor and Municipality and the Queen's University of Belfast. It will be presided over by the Marquess of Londonderry, Chancellor of the University. The inaugural meeting will be held on the morning of Tuesday, May 10th, and the scientific work of the congress will be conducted in the following Sections: State medicine and municipal hygiene (including port sanitation); Industrial hygiene; Women and children and the public health; Tuberculosis; Pathology, bacteriology, and biochemistry. Delegates are being invited from the Governments, the municipalities, the universities, and other public bodies of Great Britain and Ireland and the British Dominions, as well as from Continental and other foreign countries. Arrangements have been made with the railway companies for a reduction in the fares.

Dr. James Cran has been appointed an unofficial member of the Legislative Council of the colony of British Honduras.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are *MUSEUM* 9961, 9962, 9963, and 9964 (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:
EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Mediocra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS

Intestinal Flatulence

"PUZZLED" writes: Could any of your readers recommend treatment for intestinal flatus in a well-nourished, but somewhat neurotic man of 35. Urine, etc., are normal. X rays show no abnormality beyond a very slight kinking of the colon. The bowels are kept easily moved by a teaspoonful of is-o-gel at nights. The flatulence begins in the mornings after defæcation, and continues all day with distension pains and general depression. Sometimes it can be dispelled by lying on the left side. He has had courses of abdominal massage and exercises, without much improvement. Temporary relief is obtained by rectal injection of two tablespoonfuls of glycerin. Are any drugs helpful? He has tried bismuth etc., without result. Might the condition be purely functional?

Painful Heel

Dr. R. C. BRISCOE (Kisumu, Kenya) writes: I have a patient suffering from a painful heel. There is no swelling or constitutional disturbance, but the patient, by deep pressure on the plantar surface of the heel, can demonstrate a definite tender spot. He has had to give up tennis on account of the pain, and is now wearing rubber heels to his shoes. I shall be glad of any suggestions for treatment.

Vomiting and Nausea of Pregnancy

Dr. L. L. STEELE (Blyth) wishes to thank the doctors and manufacturing chemists who replied to his query in a recent issue of the *Journal*. The replies, he says, are too numerous for individual attention.

Pseudo-Hermaphroditism

Mr. G. S. WOODMAN writes from the Royal Hospital, Baghdad:
In reply to Messrs. Neal and Cox's query of October 31st (p. 832) with reference to my memorandum on pseudo-hermaphroditism, in the *Journal* of October 24th (p. 750), the following were the secondary sexual characteristics in this case. The breasts resembled in size those of an obese male, the nipples and areolae were distinctly smaller than those of the average female. Pubic hair was scanty, and the voice definitely masculine. With the exception of a degree of superficial hypogastric adiposity not in conformity with that of the rest of the body, the general conformation was that of a stocky male. A short bull neck, masculine face with a few hairs on upper lip and chin, broad shoulders, deep chest, muscular upper and lower extremities, with powerful hands and broad feet, and an absence of any trace of female genu valgum, were the outstanding general features of the case. The mental outlook was apparently that of a female, and a prolonged inquiry failed to elicit any evidence of preference for the female sex.

Income Tax

Cash Basis—Cessation of Practice

"P. P. A." has been assessed for the past twelve years on the cash basis. He has sold his practice as from November 1st, 1931, and has been asked to put in statements setting out his profits on an "accounts" basis for the year to April 5th, 1931, and the period from that date to October 31st, 1931.

** Under the law now in force "P. P. A." can be required to submit to a revision of his liability for the two periods specified from the statutory basis of the previous year to the "actual" year. At the same time he cannot be required to prepare special accounts for the period merely because his existing accounts are made up to some date other than April 5th. For instance, if his accounts throughout had been on the basis of bookings less allowances for bad debts instead of on the cash basis, the new calculation would have been: (*a*) for 1930–31—three-quarters of the 1930 profit plus three-tenths of the profit for the ten months from January 1st, 1931, to October 31st, 1931; and (*b*) for the final period from April 5th, 1931—seven-tenths of the last-mentioned profit. The chief question to be faced is whether the inspector of taxes can properly require the cash basis to be thrown over for the purpose of the contemplated adjustment of liability, bearing in mind the extreme difficulty of arriving now at any reliable estimate of the value of the debts outstanding at January 1st, 1930, January 1st, 1931, and October 31st, 1931. If the work of the practice was growing during that period, or, for some reason, receipts were coming in at a slower rate than normal, then the cash basis would show a smaller profit than was really being earned. In that case the revenue authorities are justified in requesting some adjustment, seeing that receipts subsequent to October 31st, 1931, will not be assessable. But if the facts do not suggest that there has been too low a "cash" profit the adjustment is unlikely to benefit the revenue, and we consider that the official request might properly be withdrawn.

Reduction in Salary

"J. J." has for some years held a whole-time appointment on a salary of £800. The salary is to be reduced by 7½ per cent. as from January 1st, 1932. What is his liability to tax for the year to April, 1932?

** On £800, that being the amount of the earnings of the "previous year," which forms the statutory basis of the assessment for the current year. When "J. J." paid tax on £800 for 1930–31 he cleared his liability up to April, 1931, but his 1931–32 income must by law be regarded for assessment as being the amount of the 1930–31 earnings.

LETTERS, NOTES, ETC.

British Hypodermic Needles

We have received the following letter from a leading firm of instrument makers:

With reference to the statement in last week's *Journal* that needles of Continental manufacture have been for "so long in general use in this country," we venture to inform you that we have never supplied hypodermic needles of foreign manufacture. The error has no doubt arisen from the fact that the well-known Record syringe is generally known as of foreign origin. However, we have always supplied British make. We have been in the habit of supplying the *all-glass* syringes, both English and French (distinctly so quoted and marked), but in this case also with English-made needles, and we are confident that most of the leading surgical instrument manufacturers do supply British-made needles.

Local X-ray Treatment of Infection

Mr. E. P. WATERS, F.R.C.S.Ed. (Barrow-in-Furness), writes: It is beyond dispute that some of the sun's rays are antagonistic to micro-organisms. For this reason I think that radiation therapy will occupy a prominent position in the future in the treatment of disease due to pathogenic bacteria. I have sometimes wondered whether exposure to *x* rays would be of any value in the treatment of such disease, more especially, perhaps, where the organisms are localized—for example, tonsillitis, diphtheria, osteomyelitis, furunculosis, phthisis, etc. Possibly some of your readers have had actual experience along the lines suggested above.

Asthma and the Endocrine System

Dr. A. K. JAMES (Calne, Wiltshire) writes: In the search for a common constitutional factor in the etiology of asthma the endocrine system has not been neglected; in this connexion the following case merits publication. A married woman aged 29, gave a history of attacks of asthma since she was 17; no family history of asthma was obtained. She had attacks at about six-weekly intervals from the age of 17 until she became pregnant in January, 1926, when the asthma ceased until January, 1927. Her next attack was about four months later, and the attacks subsequently became much more frequent—in 1929 and 1930 on an average every three or four weeks. All the usual investigations were negative. Treatment by all usual methods, including whole-blood injections, ultra-violet light, glucose, etc., was of no benefit. In view of the fact that the only period during which the patient had been free from attacks was during her one pregnancy, treatment by thyroid and corpora lutea in tablet form was begun in October, 1930, with striking success. The patient has now been completely free from asthma for the last thirteen months, and has put on 1 st. 3 lb. in weight.

New Motor Regulations

The Automobile Association draws attention to the following new regulations affecting motorists, which come into force on January 1st next. Every motor vehicle (motor cycles excepted) must be fitted with a reflecting mirror, so that the driver may be acquainted with the proximity of vehicles about to overtake. All glass fitted to windscreens or windows facing to the front on the outside of any motor vehicle, except glass fitted to the upper deck of a double-decked vehicle, must be safety glass. Vehicles registered before 1932 are exempt until 1937, but meantime the glass fitted (safety or otherwise) must be maintained in a condition which does not obscure the driver's vision. "Safety glass" is defined as glass which, if fractured, does not break into fragments capable of causing severe cuts. Motor vehicles (except motor cycles or mobile cranes) registered after January 1st, 1932, and any trailer constructed after June 1st, 1931, must be equipped with suitable and sufficient springs between each wheel and the frame of the vehicle. The *Motorist's Legal Guide*, available free of charge to A.A. members, deals with these and other points of importance to motor owners. Any motorist who is in doubt as to the effect of the new regulations should communicate with the A.A. Legal Department, Fanum House, New Coventry Street, W.1.

Vacancies

Notifications of offices vacant in universities, medical colleges and of vacant resident and other appointments at hospitals will be found at pages 41, 42, 43, and 46 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 44 and 45.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 331.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

565 Asymptomatic Subacute Bacterial Endocarditis

G. L. West (*New England Journ. of Med.*, October 1st, 1931, p. 675) reports a case illustrative of the wide variations between the ordinary course of subacute bacterial endocarditis and the asymptomatic course. This case presented the classical pathological findings in the endocardium, but no symptomatology was noticeable until a few minutes before death, when embolism of the coronary artery occurred as a direct result of the ulceration and detachment of the vegetative growth. A healthy athletic woman suddenly stopped playing tennis, her body relaxed, she became unconscious, and died within half an hour. She was an athletic instructor, a regular swimmer, and an equestrian. She had never been known to make any physical complaint Three years before her death she had consulted a physician for a wrench of the neck muscles due to an automobile accident. Her past history only revealed that she had once been thrown from her horse, and was supposed to have had malaria. The post-mortem examination brought to light no abnormalities except in the heart and kidneys. The endocardium was normal apart from the region of the aortic valve, on the under surfaces of all the aortic cusps were friable vegetations The anterior cusp showed a vegetative growth 2 mm in length, 2 mm. wide, and 5 mm. thick; it was red in colour, and easily detachable. A single vegetation occupied the under surface of the other two aortic cusps. This mass had ulcerated, and had left a deep ulcer with irregular roughened walls At the bifurcation of the left coronary artery was found the cause of death, an embolus of vegetative growth from the aortic valve, resting in such a way as to occlude both branches distal to the bifurcation. The kidney sections revealed healed glomerular embolization, and the lungs were oedematous. The growth showed a few Gram-positive cocci growing singly and in chains, but no cultures were obtained from the blood or from the vegetations

566 The Influence of Resident Hospital Treatment on Asthma

H. C Gram (*Nordisk Medicinsk Tidskrift*, October 3rd, 1931, p 625) produces statistical evidence on behalf of his thesis that the prophylaxis of asthma is essentially a problem of social conditions, and that success is to be achieved in this field primarily by rational hygiene in the home. It is common for severe cases of asthma to be cured in one to three days simply by the patient being admitted to a good hospital, which may, for that matter, be next door to the patient's own home. These dramatic recoveries, he remarks, are quite independent of any or every special treatment given in the hospital, the staff of which is apt to question the judgement and veracity of the practitioner who has sent the patient to hospital with a report of violent and prolonged asthmatic crises In the sickness insurance records in his possession, the author has notes on 366 asthmatics who were admitted to hospital In as many as 187 cases, hospital treatment proved beneficial This improvement may have been due to one or more of the three following factors. The patient may be sensitive to certain specific factors, domestic animals, or articles of food, with which he does not come in contact in the hospital. It is, however, rare for such sensitiveness to be strictly specific and limited to a single object Secondly, admission to hospital often entails the breathing of a different kind of air. The patients who recover temporarily on account of this factor would do so equally well if they were admitted to a private house in the same locality as the hospital. Thirdly—and this is probably the most frequent cause of the relief of symptoms which hospital treatment confers—the modern hospital has light and dry wards, kept scrupulously dust-free. The bedding is frequently disinfected, and thus the development of organic life in it is prevented. The author insists that it is impossible to overestimate the importance of these factors in the prevention and treatment of asthma.

567 Streptococcaemia and Latent Tuberculosis

G. Denes (*Studium*, September 1st, 1931, p. 359) considers that the infective acute stage which precedes the usual manifestation of tuberculosis is not to be attributed to a filterable tuberculous virus, but to other organisms, especially streptococci; an acute streptococcal infection, not itself fatal, can bring about the activation of latent tuberculous foci, and cause an extension of that infection. Two cases are described, one of acute tonsillitis, the other of an injury to the heel, from both of which non-haemolytic streptococci were recovered by blood culture. After recovery from the septicaemia, both patients developed in the course of a couple of months symptoms of tuberculosis, which soon ended fatally. Before the streptococcal infection there had been no tuberculous signs in either of these cases.

568 Paraplegia following Measles

L. Babonneix and F. B Levy (*Bull. Soc. de Péd*, July, 1931, p. 371) record the case of a boy, aged 5½, who a few days after a mild attack of measles developed complete quadriplegia, with involvement of the nuchal muscles, sphincter disturbances (retention and obstinate constipation), anaesthesia of the lower limbs, and Babinski's sign. In the course of a fortnight considerable improvement took place, the paralysis being confined to the lower limbs Since diphtheria and infantile paralysis could be excluded, the authors attribute the condition to an acute myelitis involving the pyramidal tract, the posterior columns, and the anterior cornua.

Surgery

569 Retroperitoneal Tumours

I Cohn (*Arch. of Surg.*, October, 1931, p. 655) reports seven cases of retroperitoneal tumour which included one case of retroperitoneal lymphoblastoma (Hodgkin's type), one of retroperitoneal lymphosarcoma, one of retroperitoneal sarcoma secondary to sarcoma of the thigh, one of retroperitoneal sarcoma without metastases, and three cases of retroperitoneal metastases following teratoma of the testicle. Diagnosis in all cases of retroperitoneal tumours is extremely difficult, but is helped by *x* rays. Symptoms depend on the site of the growth; proximity to the coeliac plexus causes digestive disturbances, and anaemia is present in many cases Oedema of the extremities and ascites are present when the growth is large and on the right side, and when it interferes with the venous return. Retroperitoneal growths may be associated with chylous ascites and chylous pleural effusions; some may present the clinical picture of an infection, such as Hodgkin's disease In the first case reported, which was retroperitoneal lymphoblastoma, the patient suffered from acute digestive disturbances with severe abdominal pain, nausea, vomiting and violent abdominal cramp, these manifestations had recurred at intervals for twenty years The diagnosis made in this case was gall-bladder disease, and cholecystectomy was performed without relief of the symptoms, after a further exploratory laparotomy the patient died The necropsy showed large retroperitoneal glands near the stomach, pancreas, and duodenum, and an ulcerating lesion of the wall of the stomach The case of retroperitoneal lymphosarcoma was associated with ascites which later became

chylous, with chylothorax, and oedema of the extremities. Paracentesis and thoracocentesis were undertaken, but the patient died; metastases were found in the mediastinum, pelvis, uterus, ovaries, spleen, and kidneys. In the case of retroperitoneal sarcoma the condition appeared to be secondary to a sarcoma on the outer side of the thigh. This was excised, and deep *x*-ray therapy was instituted for the retroperitoneal involvement; after further operations fatal oedema and respiratory troubles developed, and metastases were found involving the entire gastro-intestinal tract, the liver, lungs, pleura, kidneys, and lumbar vertebrae. One case of retroperitoneal sarcoma is reported in which no metastases were found, but the patient died shortly after an exploratory laparotomy. The remaining three patients were suffering from teratoma of the testicle with retroperitoneal metastases. Of these, two were treated by orchidectomy with high ligation, followed by applications of radium, and the persistent use of *B. pro-digiosus* toxins. These patients remained in good health for two and five years respectively. The remaining patient died some months after operation. The author points out that the mortality rate for all cases of retroperitoneal tumour is extremely high.

570 Diagnosis and Treatment of Appendicitis

V. PAUCHET (*Bull. et Mém. Soc. Méd. de Paris*, October 9th, 1931, p. 478) states that Soresi's sign is a very important diagnostic aid in appendicitis. With the patient in the prone position the surgeon places his right hand vertically in the nipple line over the right hypochondrium, and the patient is told to cough. If pain is felt in the appendix region, the diagnosis is confirmed. The explanation is that pressure applied thus to the abdominal muscles is transmitted to the colon, and the gas contained therin causes pain on coughing in appendicitis. This method is said to be preferable to the usual application of pressure to the appendix region, and to exclude psychic elements. The author strongly recommends the latero-posterior incision in appendicectomy; he has employed it for two years with most satisfactory results (only one death in nearly 400 cases). The incision commences at the iliac crest, and is carried forwards for two to four inches parallel to that landmark. The external oblique fascia is divided, and the fibres of all the subjacent muscles are separated, but never cut. The peritoneum is incised parallel to the skin incision. The caecum is exposed, and is raised until the base of the appendix appears. Whatever may be the position of the appendix it can always be found and removed when its base is exposed. The serious complication of retrocaecal appendix becomes quite simple when the latero-posterior incision is employed. An appendicular abscess can be evacuated completely without infecting the peritoneum. In general peritonitis, dependent drainage is secured by the incision; when adhesions are present, complications do not follow, post-operative hernia never ensuing. Pauchet adds that the Trendelenburg position should always be employed, and that this incision is suitable only for appendicectomy; it should not be used in exploratory laparotomy, or for the removal of any other abdominal organ.

571 The Spastic Colon and Abdominal Pain

Chronic or recurrent abdominal pain, with few or no objective signs, presents a difficulty as regards the diagnosis between an organic and functional cause, and chronic colospasm or spastic colon has been a frequent cause of unnecessary operations. F. L. APPERLY (*Australian and New Zealand Journ. of Surg.*, September, 1931, p. 192) records a study of this condition based on 45 cases. The affection is usually considered to preponderate in females and in asthenic types; the reverse of this, however, was found in the present series. The majority of the patients were nervous and neurasthenic, and many showed allergic manifestations. Various predisposing causes are cited, and the frequency of past, unsuccessful abdominal operations is noted. The commonest symptom is pain and discomfort of varying intensity and duration; it may appear over any part of the abdomen, but the commonest sites are the right and left iliac fossae, the left side being more often concerned. Constipation is common; some cases are normal, however, as regards bowel action, and a few have diarrhoea. Reflex phenomena, such as pylorospasm and bradycardia, may occur. Gastric symptoms appear in most cases, and other symptoms such as headache and insomnia are frequently noted. Physical examination reveals little, and the gastric acidity varies greatly. The chief conditions to be differentiated are enumerated, and the pathology is briefly discussed. Treatment is medical rather than surgical.

Therapeutics

572 Combined Treatment of Chronic Syphilis

Since the general adoption of serological tests as guides in the routine treatment of syphilis, many cases presenting persistently positive reactions have been recorded. Repeated courses of anti-syphilitic treatment frequently fail to produce a permanently negative reaction in the serum and cerebro-spinal fluid, and many patients subsequently develop cardio-vascular or neural syphilis. In chronic latent syphilis with constantly positive Wassermann reaction, when ordinary treatment has been ineffectual, and also in cardio-vascular and neurosyphilitic cases (most frequently tabetic) in which specific and non-specific treatment has failed, E. RAJKA and E. RADNAI (*Ann. de Derm. et de Syph.*, September, 1931, p. 956) have obtained good results from actinotherapy, either alone, or with intra-gluteal injections of the patient's own blood, withdrawn thirty minutes after the commencement of irradiation. The entire body is exposed to an erythema dose thrice weekly for ten weeks. Blood is withdrawn during the first and last ten of a course of thirty irradiations, and is injected intramuscularly in increasing doses of from 2 to 15 c.cm. In latent syphilis 57 per cent. of positive Wassermann reactions became negative; in neurosyphilis, this result followed in 28 per cent. of cases. This negative phase persisted for periods of from two months to three years, but later some cases became positive. The treatment increased the blood-calcium content. In 41 cases of neurosyphilis with aortitis, the subjective symptoms improved constantly. Remissions lasted for one to nineteen months. Relapses occurred in 22 per cent. of cases, but a second course reduced relapses to 12 per cent. The procedure described improved the patients' general health and vigour, but objective symptoms generally persisted. The treatment should be repeated at regular intervals, since this appears to render amelioration permanent. The authors have not substituted their method for those already employed in the routine treatment of syphilis, but they recommend its use in refractory cases.

573 Hypertonic Salt Solution in Post-operative Anuria

Vomiting may bring about such an excessive loss of chloride from the body as to induce prolonged anuria, with grave consequences. H. F. ROOT and P. P. HENSON (*Journ. Amer. Med. Assoc.*, August 22nd, 1931, p. 540) report a case of post-operative anuria in which relief was obtained by giving intravenous injections of a hypertonic saline solution after the subcutaneous introduction of normal saline solution had failed to produce any benefit. A boy, aged 5, was operated on for acute uncomplicated appendicitis, and about two days after the operation passed urine containing acetone in large quantities, with slight traces of albumin and sugar. Anuria then ensued for four days, the bladder remaining empty; there was vomiting, but the bowels were open. The non-protein nitrogen of the blood was 162 mg. per 100 c.cm., and the blood plasma chloride 248 mg. After the failure of dextrose administration, intravenous injection of normal saline solution, and the introduction of tap water into the rectum, 60 c.cm. of a 10 per cent. solution of sodium chloride was injected intravenously. Four hours later the patient passed 120 c.cm. of urine, thus terminating an ill-

of suppression which had lasted for 97 hours. He complained of thirst and hunger, and took food and fluids freely; in the next fourteen hours he passed nearly 3,000 c.cm. of urine; subsequent progress was uneventful. The authors remark that this suppression was apparently due to a reduction of the plasma chloride to a level where urinary secretion ceased—the consequence of continued vomiting with marked chloride loss. The amount of chloride needed to replace this was doubtful, because 15 grams had been given subcutaneously; this was either retained in the tissues or lost in the subsequent vomiting. The salt deficit in the blood was calculated from a theoretical estimate of the total blood volume, associated with the plasma chloride content estimation, and two-thirds of the dose thus indicated was given with excellent results. In such cases of vomiting and acidosis the authors stress the importance of blood plasma examination so that salt deficiency can be corrected without delay.

574 Vaccine Therapy in Whooping-cough

E. J. SCHMITZ (*Deut. med. Woch.*, October 16th, 1931, p. 1784) remarks that among the numerous remedies recommended for whooping-cough, no specific has been found, but many satisfactory results have been reported from vaccine therapy, which appears to mark a definite advance. He has found it necessary to divide the patients into two classes—namely, infants and children of school age. Vaccines were used for prophylaxis, as well as for treatment. At first a mixed vaccine was employed, but in several instances this appeared to aggravate the catarrhal symptoms; in some cases the temperature rose to over 102° F. A pure whooping-cough vaccine was then tried, commencing with a minimal dose of 2,000 millions and increasing the dosage rapidly to the largest doses—8,000 or 10,000 millions—after two or three days. Among the 38 infants so treated, the vaccine had no effect in five cases; in two instances the results were doubtful. In all the remaining cases the effect was favourable. Schmitz found that the best results were obtained in the early stages of the disease, and that it was necessary to continue the injections, even when a single dose gave relief. No ill-effects were observed, even after the largest doses of the vaccine.

Radiology

575 Meningitis produced by Iodized Oils

The injection of lipiodol and of other iodized oils for skiagraphic purposes is not free from danger. A. F. LINDBLOM (*Acta Med. Scand.*, September 30th, 1931, p. 395) has endeavoured to find a non-irritant iodized oil, suitable for myelography, and to ascertain the oily components causing chemical meningitis. The experimental animals (rabbits) showed considerable variation in reaction. Four rabbits received subarachnoid injections of 0.5 c.cm. of iodized poppy oil (acidity 2.5); two died of acute meningitis within 24 hours; two were moderately affected for two days, and when killed three days later, aseptic meningitis was found. The presence of catalytic agents may be important. Experiments showed fundamental differences between iodized vegetable and animal oils. Various vegetable oils differed in effect—for example, sesame oil caused slight irritation, while poppy oil produced severe meningitis owing to the presence of varying percentages of free fatty acids. When iodized sesame oil with a varying acidity content was used, the resultant irritation was proportionate. Iodine increased irritation by combining with free fatty acids. Hydriodic acid is formed by hydrolysis, during or after preparation of the iodized oil, being increased by higher temperatures and by iodine saturation of the oil. After injection of iodized oil, the iodine compounds are absorbed, usually in a few days, but free oil may be retained for years, either in bulk or as numerous small droplets, producing pachymeningitis. The effects of injecting animal oils are entirely different. Iodized cod-liver oil is emulsified in 24 hours after injection. The animals generally died in one or two days, but some improved after resorption of the oil; meningitis was due to decomposition products such as oxy-acids and glycerin, and for this reason animal oils are unsuitable for skiagraphic purposes. Lindblom concludes that iodized oils should be used only when clearly indicated, and not as a routine procedure.

576 Treatment of Ureteral Fistula

According to A. WALTER and K. DECKNER (*Zentralbl. f. Gynäk.*, October 3rd, 1931, p. 2946), suppression of the function of one kidney by *x*-radiation in large doses was first recommended by Klein in 1928, and was inspired by the finding of Kraemer that a parotid fistula became healed after radiotherapy. About a dozen cases of success of the treatment have been described, in one of which it was found that function of the irradiated kidney persisted after closure of the fistula. Six unsuccessful cases have been reported; in one of them the subsequently excised kidney was pyelonephritic, and in another the histological features of the kidney did not differ from those of other (non-radiated) pyonephroses. The present authors record a case in which a kidney was removed after its unsuccessful radiation for ureteral fistula; early fibrotic and also inflammatory conditions were found throughout, together with signs of ascending pyelonephritis. In two other instances, accidental division of the ureter at operation was treated by knotting of the ureter, and on the same and subsequent days by *x*-radiation of the kidney. In neither case did a fistula occur. In one which eventually came to necropsy, the kidney was free from infection, and showed macroscopically and microscopically no other abnormality than a slight hydronephrosis. It should be remembered that spontaneous healing of a ureteral fistula is not uncommon; it seems possible that *x*-radiation of the kidney may promote healing without annulling renal function in the manner demonstrated in animal experiments.

577 O. JÜRGENS (*Bull. Soc. d'Obstét. et de Gynécol. de Paris*, October, 1931, p. 664) reports a case in which a ureteral fistula following a gynaecological operation became closed eight days after radium application. Renal function on the other side had been previously proved to be satisfactory. Before the treatment the ureteral orifice had functioned continuously, though partially, but after irradiation it ceased transmitting urine—a confirmation of Klein's contention that an atrophic sclerosis of the kidney is induced.

578 Radiotherapy with Internal Medication in Localized Decalcifications

According to G. CHAUMET (*Journ. de Radiol. et d'Électrol.*, September, 1931, p. 510) *x* rays are known to benefit certain osteo-arthritic conditions; ultra-violet rays have been employed in the treatment of rickets and other osseous conditions, and phospho-calcium salts have been long exhibited in tuberculosis and various skeletal deficiencies. It was thought that a combination of these agents should be beneficial, and Chaumet has obtained happy results by this method in infective osteo-arthritis, in articular rigidity with decalcification following long immobilization, and in retarded union of fractures. His technique is as follows. Small doses of *x* rays are given daily or on alternate days over the same field of the affected member. At each treatment 150 R under 15 mm. aluminium, with a tension of 130 kV, and an anti-cathode-skin distance of 22 or 31 cm., are given until a total of 1,800 to 2,000 R is reached. The number of fields depends on the size of the region. The rhythm of the treatment is so determined that the *x*-ray series corresponds to the duration of the ultra-violet series—namely, 40 days. The latter rays are applied every two days in large thoraco-abdominal irradiations, first anteriorly, then posteriorly. These irradiations are progressively increased from a duration of 4 or 5 to 25 or 30 minutes, and the distance of the lamp is decreased from 1.5 to 0.9 metre. The series consists of 18 to 20 treatments. The patient's reactions are a guide in treatment; erythema is not desired, and fever or nocturnal agitation must be avoided. During the 40 days of treatment the patient is given tricalcine or similar medication orally.

Obstetrics and Gynaecology

579 Post-menopausal Haemorrhage and Ovarian Tumours

That uterine bleeding in patients beyond the menopause who show no gross abnormality of the uterus may be an early sign of ovarian tumour has been pointed out by Moulonguet-Doléris, R. Meyer, Neumann, and others; it has been described as being specially associated with the type of diffuse primary carcinoma of the ovary known as granulosa-cell tumour. K. TIETZE (*Arch. f. Gynäk.*, August 10th, 1931, p. 197) finds that in 50 per cent. of malignant post-menopausal ovarian tumours metrostaxis is present, but it is sometimes due to other causes than the ovarian tumour, such as uterine polypus. In a series of 71 cases of ovarian tumours of all sorts in women beyond the menopause, 23 per cent. had uterine haemorrhage, and all these had a malignant tumour. Of 12 cases fully investigated the metrostaxis was associated in 4 with granulosa-cell tumour of the ovary; in these cases there was also marked hyperplasia of the uterine muscle, endometrium, and tubal mucosa. The uterine changes are probably due to hormonic influences from the diseased ovary; Schuschania and Siebke proved this to be so in one of Tietze's cases by demonstrating in the urine large amounts of folliculin before but not after the operation.

580 Sudden Alteration of the Blood pH during Delivery

H. SIEDENTOPF (*Zentralbl. f. Gynäk.*, October 24th, 1931, p. 3117), measuring the hydrogen-ion concentration, the acetone content, and the β-oxybutyric acid content of the blood during labour, found that these increased on the whole very slightly during the relatively long course of the first and second stages. In the relatively short period, however (nine minutes as an average), corresponding to the expulsion of the foetus at the end of the second stage, there occurred an acute and substantial shifting of the blood composition towards the acid side, with much rapid increase of the *p*H, and of the acetone and β-oxybutyric acid content. After considering possible explanations of this sudden change, he concludes that it is due to the acute shrinkage of the uterus, and the expression from this into the general circulation of large amounts of blood and lymph laden with products of katabolism. In confirmation is reported a sudden increase of the non-protein nitrogen of the blood during expulsion of the foetus.

581 Pregnancy Complicated by Goitre

R. D. MUSSEY and W. A. PLUMMER (*Journ. Amer. Med. Assoc.*, August 29th, 1931, p. 602) find that the use of small doses of iodine is of value in the treatment of colloid goitre during pregnancy; that hyperthyroidism responds satisfactorily to the administration of thyroid extract (under careful observation); and that adenomatous goitre, uncomplicated by hyperthyroidism, rarely needs treatment during pregnancy, although both adenomatous and colloid goitre may produce sufficient venous or tracheal pressure to necessitate partial thyroidectomy. Hyperthyroidism, resulting from adenomatous goitre, is often not satisfactorily controlled by iodine, and it is then safer to remove the adenomatous tissue. The use of the compound solution of iodine in doses of 10 drops three times a day in cases of exophthalmic goitre should be followed by distinct improvement, including a definitely c. lowered basal metabolic rate, within a fortnight. Patients *lia* must, however, be watched carefully, and repeated p. 1 etabolic rate determinations be made, since recrudes-The ace of the disease often occurs in spite of the con-females and inition of iodine. Except in certain cases in ever, was found nths of pregnancy, partial thyroidectomy the patients were rmed without delay if the exophthalmic showed allergic n show complete, or nearly complete, causes are cited, and wo weeks after the institution of iodine abdominal operations ay be followed by irreparable damage is pain and discomfort hen the strength of the patient is it may appear over any

diminished, or the heart is injured as a result of the severity of the hyperthyroidism, it may be necessary to shorten labour by forceps or version, or, rarely, by Caesarean section. Whereas, formerly, interruption of pregnancy was usually advised when severe hyperthyroidism was present, and miscarriages occurred spontaneously in the absence of treatment, it has now been shown that partial thyroidectomy in adenomatous goitre with hyperthyroidism (and, since 1922, the use of iodine in exophthalmic goitre, followed by partial thyroidectomy, when indicated) enables pregnancy to be continued safely and effectively.

Pathology

582 Testing for Immunity to Yellow Fever

W. A. SAWYER and W. LLOYD (*Journ. Exper. Med.*, October 1st, 1931, p. 533) have elaborated the test described by Theiler for demonstrating immunity to yellow fever. Theiler mixed the suspension of virus and the serum to be tested, and injected them intracerebrally into white mice, using six or more mice for each test. Fairly satisfactory results were obtained, but many mice died, presumably from simple trauma of the brain tissue, and excessive numbers of animals had to be used to obtain reliable results. The present authors have found that more satisfactory results can be obtained by injecting the virus-serum mixture intraperitoneally, at the same time introducing a small quantity of starch emulsion into the brain to assist in the cerebral localization of the virus. If the serum lacks protective power, the mice die of yellow fever encephalitis, usually between the fifth and tenth days. The test is highly sensitive, and is likely to be of considerable value in survey work to ascertain the extent of endemic yellow fever in various districts. It may also be used to determine whether artificial vaccination has led to the development of immune bodies. It is necessary to employ a strain of virus that has been passed through a large number of mice in series so as to render it more or less fixed. The actual strain of mouse used likewise seems to be of importance, since some strains appear to be much less susceptible than others.

583 Food Poisoning Apparently due to Staphylococci

E. O. JORDAN and J. R. HALL (*Journ. Preventive Med.*, September, 1931, p. 387) record a small outbreak of food poisoning due to the consumption of chicken gravy. Two members of the family who partook of the gravy developed severe symptoms in about three hours; the third member, who did not do so, showed no signs of illness. Examination of the gravy failed to reveal any members of the Salmonella group, but colonies of staphylococci were abundant, belonging to the *S. aureus* type. Experiments made on human volunteers with the filtrate of a 72 hour broth culture of this organism gave interesting results. Six volunteers, at some time during a period of nine weeks following the preparation of the filtrate, were fed with 5 c.cm. of the filtrate in a glass of milk. Four of them developed acute symptoms about three hours later with vomiting and diarrhoea; the other two showed no symptoms. The close correspondence as regards the symptoms and in the incubation period between the volunteers and the original victims suggests very strongly that the products of growth of the staphylococci in the food were responsible for the outbreak described. In another paper, E. O. JORDAN, G. M. DACK, and O. Wo[illegible] (ibid., p. 383) report the results of experiments made to determine the heat resistance of staphylococcus [illegible]. The experiments were conducted on a small scale and showed that though some diminution in toxicity may be caused by heating even at temperatures below [illegible] sufficient toxicity might remain after exposure for minutes at the temperature of boiling water to cause severe and characteristic symptoms when fed to [illegible] in 2 to 10 c.cm. quantities.

Before the Operation and After

In preparation for the operation  one tablespoonful of Agarol on retiring  in place of the usual castor oil, will insure against gastric upset.  Again, a few days later  when the patient begins to take nourishment  Agarol in half doses  is the logical eliminant because it stimulates peristalsis  gently without griping or pain.

AGAROL Brand Compound is the original mineral oil and agar-agar emulsion with phenolphthalein. It softens the intestinal contents and gently stimulates peristalsis.

Agarol Brand Compound is palatable without artificial flavouring and easy to take. The usual dose in chronic constipation is a tablespoonful, reduced as improvement takes place.

A supply gladly sent for trial.

AGAROL BRAND COMPOUND *for Constipation*

"The Rose Corset-Belt"

for Accurate Abdominal Support and Comfort

Extract from the "British Medical Journal," Dec. 10th, 1927—

'Visceroptosis is the cause of so much discomfort and ill-health . . and an ill-fitting or wrongly applied belt or corset may aggravate rather than diminish the subjective effects of this condition . Madame Rose has for many years devoted special attention to this problem and we have good reason to believe that she has given help and comfort to a considerable number of sufferers We have received assurances from medical men, who have sent patients to her, that she gives personal attention to each patient, that she takes great care in adapting and adjusting the support to the particular needs of the case."

President LORD WAKEFIELD OF HYTHE, C.B.E., LL.D.
Treasurer SIR LIONEL FALDER-PHILLIPS, Bart.
Physician-Supt: J. G. PORTER-PHILLIPS, M.D., F.R.C.P.

This Registered Hospital is now situated at Monks Orchard, in some 250 acres of park, pleasure, and farm grounds.
Applications can be considered on behalf of patients of the educated classes in a presumably curable condition.
With a view to early treatment voluntary or uncertified patients are admitted.
Patients who can contribute 5 guineas weekly towards the cost of treatment and maintenance may be received as vacancies arise. The Committee will also consider applications for admission at lower rates, and in certain cases will be prepared to admit patients free of charge.
Every facility for specialized investigation and treatment is provided in the Lord Wakefield Science and Treatment Unit. In this Unit is found the X-ray and Dental Departments and the Bio-Chemical, Pathological, and Psychological Laboratories.
Furthermore, provision is made for Electro-Therapy and Hydro-Therapy to be carried out in all their forms.
In addition to the Resident Medical Staff, Consultants in special branches of Medicine and Surgery are available whenever required.
The comfort of sensitive patients is greatly enhanced by the fact that the majority are given single bedrooms.
For forms and further particulars apply to the Physician-Superintendent at the Hospital.

RUTHIN CASTLE, NORTH WALES

REDUCTION OF FEES

In view of the present economic position, the inclusive fees at Ruthin Castle, formerly from 17 guineas a week, have been reduced to from 15 guineas a week.

The fees include medical attendance, all scientific investigations that may be needed, such as analyses, bacteriological cultures, the ordinary x-ray examinations, and electrocardiograph readings, all treatment that may be prescribed, such as special diets, insulin, artificial sunlight, electrical treatment, baths, massage, nursing, medicines or vaccines, board and lodging.

The only extra charge is that for a complete alimentary x-ray examination, or for x-ray therapy.

Many people who would go abroad for health will not do so this winter. All the usual forms of treatment are given at Ruthin Castle. The climate is mild. The annual rainfall is 30·5 inches, that is, less than the average for England. There is central heating throughout. Should the accommodation in the Castle not prove sufficient, comfortable rooms can be obtained near by for those undergoing treatment.

Address—THE SECRETARY, Ruthin Castle, North Wales. *Telegrams:* CASTLE, RUTHIN. *Telephone.* RUTHIN 66.

HOVE VILLA, BRIGHTON—CONVALESCENT BRANCH OF THE ABOVE.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or who wish to prevent recurrent attacks of mental trouble, temporary patients, and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms, with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary and Temporary Patients received.

Tel.: 64117. *For terms, etc., apply to the Medical Superintendent.*

HAYDOCK LODGE,
NEWTON-LE-WILLOWS, LANCASHIRE.

'Phone: 11 Ashton-in-Makerfield.

For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES either voluntarily or under Certificate. Patients are classified in separate buildings according to their mental condition.

Situated in park and grounds of 400 acres. Self-supported by its own farm and gardens, in which patients are encouraged to occupy themselves. Every facility for indoor and outdoor recreation. For terms, prospectus, etc., apply MEDICAL SUPERINTENDENT.

TYKEFORD ABBEY, NEWPORT PAGNELL,
BUCKS.
FUNCTIONAL NERVOUS DISORDERS, MEDICAL & CONVALESCENT CASES.

INDIAN MEDICAL SERVICE

Recruitment of European Officers.

Applications are invited from medical men for permanent commissions in H.M.'s Indian Medical Service. The terms offered include a gratuity of £1,000 on retirement after six years' service, or £2,500 after 12 years' service, together with free return passages for those who no longer desire to remain in the Service. In other respects the terms will be as detailed below.

Candidates must be British subjects under 32 years of age at the time of application, and must be registered under the Medical Acts in force in Great Britain and Northern Ireland.

CAREERS.

The Indian Medical Service offers wide opportunities of medical experience, including clinical, preventive, specialist, and research work. At the beginning of his career an officer is employed on the military side, which has medical charge of the Indian Army. Promotion is on a time scale up to the rank of Lieutenant-Colonel, and by selection to the ranks of Colonel and Major-General. An officer may apply after one year's Indian service to have his name registered for transfer to the civil side, from which appointments are made to Civil Surgeoncies, which are established at the principal civil centres to provide for the medical needs of civil officials and for general medical administrative purposes; to specialist (for example, public health and bacteriological) services; to research posts; and to professorships at the Medical Schools.

NOTE.—It is not possible to state at present what, if any, prospects of employment on the civil side will be open to Indian Medical Service Officers under the proposed new constitution for India.

PAY.

Owing to the state of financial emergency at present prevailing in India the existing monthly rates of pay, which are as follows, are being subjected, under the authority of the Secretary of State in Council, to a temporary reduction not exceeding 10 per cent.

Rank.	Service in Rank.	Basic Pay.	Overseas Pay.	Years of Total Service.
1	2	3	4	5
		Rs.	Rs.	
Lieut.	—	500	150	1st
			150	2nd
Capt.	(i) During first 3 years' service as Captain		150	3rd
		650	150	4th
	(ii) With more than 3 and less than 6 yrs.' service as Captain		£15	5th
		750	£15	6th
	(iii) With more than 6 years' service as Captain		£25	7th
			£25	8th
Major	(i) During first 3 years' service as Major	850	£25	9th
			£25	10th
			£30	11th
	(ii) With more than 3 and less than 6 years' service as Major	950		12th
	(iii) With more than 6 years' service as Major	1100		
Lieut.-Col.	(i) Until completion of 23 years' total service	1250		
	(ii) During 24th and 25th years' service	1500	£30	13th and over
	(iii) After completion of 25 years' total service	1600		
	(iv) When selected for increased pay	1700		
		1850		

EXTRAS.—In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the Indian Medical Service. Special high rates of pay are also attached to the numerous administiative appointments open to officers in both branches of the Service.

ANTEDATES IN COMMISSION.

Any service rendered by an officer during the war as a medical or combatant officer, or in a position usually filled by an officer, may be counted as service for increments of pay, promotion retirement and retired pay, but not for gratuity.

One half of any service in the ranks during the war may be counted as service for retirement and retired pay only.

Candidates possessing certain higher medical qualifications may be granted an antedate of one year in their commissions. Past service in certain hospital appointments may also render candidates eligible for an antedate of one year. Persons holding or about to hold resident posts at recognized hospitals may be seconded in those posts for a period not exceeding one year. The maximum period of antedate, secondment, or antedate and secondment combined, admissible under this paragraph, is limited to one year.

OUTFIT ALLOWANCE.

Officers on appointment will receive an allowance of £ towards the cost of outfit.

PRIVATE PRACTICE.

With the exception of Administrative Officers, military or civil, and officers holding certain special appointments, officers are not debarred from taking private practice, so long as it does not interfere with their proper duties.

LEAVE.

Leave can be taken at reasonable intervals, and adequate rates of leave pay are provided. Extra leave (known as study leave), which may not exceed 12 months in all during an officer's service, may be granted to officers desirous of pursuing special courses of study of a post-graduate nature. During such leave, study allowance, at present fixed at the rate of 12s. a day in the United Kingdom, £1 a day on the Continent of Europe, and £1 10s. a day in the United States of America, is granted to an officer in addition to ordinary rates of leave pay.

PENSIONS.

The rates of pension are as follows:

	Per annum.
	£
After 17 years' service for pension	400
,, 18 ,, ,, ,, ...	430
,, 19 ,, ,, ,, ...	460
,, 20 ,, ,, ,, ...	500
,, 21 ,, ,, ,, ...	540
,, 22 ,, ,, ,, ...	580
,, 23 ,, ,, ,, ...	620
,, 24 ,, ,, ,, ...	660
,, 25 ,, ,, ,, ...	700
,, 26 ,, ,, ,, ...	750
,, 27 ,, ,, ,, ...	800

These rates are subject to alteration on account of a rise or fall in the cost of living as compared with the year 1919 to an extent not exceeding 20 per cent. in all. With effect from October 1st, 1931, a reduction of 8½ per cent. has been made on this account from the amounts shown.

There are additional pensions ranging from £65 to £300 per annum for officers who have held administrative appointments.

PASSAGES.

An officer on appointment is provided with free passages to India. The wives and families of officers who are married prior to the date of the officers' embarkation on first appointment will also be provided with free passage to India, subject to the payment of messing charges.

Officers and their families are also eligible for passage concessions under which they are granted a certain number of return passages home at Government expense during their service.

INSTRUCTION PRIOR TO EMBARKATION.

Officers are required to undergo courses of instruction at the Royal Army Medical College and at Aldershot lasting approximately six months, prior to their embarkation for India on first appointment.

Full details regarding these appointments and forms of application may be obtained from the Under-Secretary of State for India, Military Department, India Office, London, S.W.1. The Selection Committee will meet at the India Office early in January next, and the selected candidates will be required to join a course of instruction commencing early in February, 1932, prior to sailing for India in the Autumn of 1932. Applications should be submitted as soon as possible.

St. Peter's Hospital for Stone, ETC.,

Henrietta Street, Covent Garden, W.C.2.

Applications are invited for appointment as CLINICAL ASSISTANT to the following members of the Honorary Staff, who attend the Out-Patient Department at the times indicated:

GREENWICH INLAID LINOLEUM
(Frederick Walton's New Patents)
COMPANY LTD.

Important New Development.

The 38th ORDINARY GENERAL MEETING of the GREENWICH INLAID LINOLEUM (Frederick Walton's New Patents) Company Ltd., was held on Monday last at 35 Newgate Street E.C.

Mr. Alexander H. Dewar (Chairman and Managing Director) presided.

The Chairman said:

In common with most industrial companies, we have had to face a difficult time in the financial year now under review. Adverse trading conditions have prevailed all over the world, and although we have more than held our own position at home our export trade has been disappointing and has suffered both in our Dominions and in Overseas countries generally.

I do not however, meet our Shareholders in any despondent mood, as I consider we are weathering the storm successfully, and when conditions improve, as improve they will, we are thoroughly well equipped to take full advantage of all opportunities to increase our trade.

In these days of considerable fluctuations in commodity prices the purchase of raw materials requires constant and expert supervision, and I am glad to assure the Shareholders that no considerable sums have had to be written off the large stocks of raw materials required in a business like our own.

During the course of the year, we found ourselves in a position to reduce our whole range of prices thus following out our policy of bringing our products within the purchasing power of the largest possible number of customers.

Our new plant and machinery came into full working order during the current year which enabled us to extend the Moderne colourings in both the Jaspe and Moire Linoleums and we have added a range of fourth Jaspe to our list. These Jaspes and Mories have commanded a ready sale both in this country and throughout the world.

New Production—"GREENOLIN."

Although Linoleum is already renowned for its wonderful wearing qualities we have been devoting our attention for some considerable time to the developments of a new production which would be an improvement under certain conditions on linoleum as it is. This special cloth we have registered under the name of Greenolin in order to associate it with the name of our own company. It is specially designed to withstand the most exacting hard wear.

We have submitted Greenolin to the most exhaustive tests and trials—it has been tested against innumerable different kinds of flooring and floor-coverings and in every case the results have been most satisfactory. We feel confident we have succeeded in producing a cloth which will meet the most trying conditions of wear.

In producing this cloth we have also been able to eliminate one of the most tedious and expensive processes of our industry—I refer to the long period of seasoning to which linoleum has to be submitted before being hard enough to send out.

The components are all thoroughly seasoned separately before being incorporated together to make Greenolin. This results in a cloth, harder and tougher than finished linoleum, within a few minutes of leaving the machine. It will therefore, be ready for delivery as soon as it is made, and it is so tough that, should customers desire it, it can be supplied without any canvas backing.

Its surface will keep cleaner and be more easily cleaned than any other floor-covering while its resistance to dampness to soaps to alkalis and to other corrosives is an important point in its favour. Having regard to its fine finish and wearing properties, we anticipate a considerable demand when the goods are placed on the market next month.

As to reviving trade at home it is certainly apparent to heads of businesses that the present crushing taxation is seriously imperilling the retail trader and until the Government of the country adjusts its finances so that the income tax can be considerably reduced, we cannot expect any great development of trade despite the efforts that are being made in all directions by business houses.

Prospects.

While it is impossible to predict what will be the result of the present monetary crisis and financial stringency that prevails the world over, we are as I mentioned in the beginning of my speech excellently equipped to take full advantage of every chance to improve our trade and your Directors are confident that with steady application and close co-operation between ourselves and our associated companies we shall win through to better results.

The report was unanimously adopted and a dividend of 6 per cent. on the Ordinary shares was declared.

Under the personal directorship of Dr. J. FIELD HALL and J. C. NEEDES

who have both had many years' experience as Medical Transfer Agents.

The commission chargeable in respect of any practice or partnership in Great Britain placed exclusively in the hands of this Agency has been fixed on an exceptionally favourable scale, the maximum chargeable on any transfer being fifty pounds (£50).

Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges. No charge is made to Principals for the introduction of Locum Tenens or Assistants.

1. OUTLYING RESIDENTIAL SUBURB.—PARTNERSHIP.—A third Partner is required in an old-established good mixed-class Practice, averaging just over £10,000 p.a., gross. A small share (to commence with) with ultimate increase, by instalments, to one-third share would be offered to a suitable partner (preferably a young married man with experience of general practice). Good house, with ample accommodation, can be purchased or rented. Premium 2 years' purchase.
2. YORKS.—LARGE TOWN.—PARTNERSHIP.—A one-fourth share is offered, after Preliminary Assistantship, in an old-established mixed-class Practice, averaging for the last three years £2,500 p.a. Panel of 1,700. Lowest fee 3/6. Suitable accommodation available. Premium 1½ years' purchase. Good scope for surgery.
3. NORTH MIDLAND CITY.—PARTNERSHIP.—Two Partners are required to take over a four-fifteenths share each (with increase later) in a very sound old-established and increasing Practice in desirable town, producing for the last 12 months at the rate of over £5,500. Panel of about 4,000. No clubs, and very little night work. Fees from 5/-. Suitable accommodation can be obtained. Premium 2 years' purchase. Excellent sport and schools.
4. LIVERPOOL.—Old-established middle-class PRACTICE, producing for the last 12 months over £1,100. Good appointments. Selected panel of 50. Fees 5/- to 21/-. No midwifery. Suitable house, with 4 reception, 7 bedrooms, bathroom, etc. Price for freehold, £1,200. Premium £800.
5. LONDON, NORTH-WEST.—Well-established middle-class non-dispensing PRACTICE, averaging for the past three years £840, including appts. worth about £300 p.a., and panel of 120. Fees 3/6 to 21/-. Large house with thirteen rooms, in addition to professional accommodation, etc. Price for freehold £3,200, £2,000 on mortgage. Prem. £1,250.
6. MIDDLESEX.—Rapidly increasing PRACTICE, in developing neighbourhood, estimated to produce about £600 in the last 12 months. Panel 500. Fees 3/6 to 12/6. Midwifery 3 to 25 gns. Good house, with 2 reception, 4 bedrooms, etc., and separate entrance to professional rooms. Good garden. Garage. Price for freehold £2,000, part on mortgage. Premium £700.
7. SOUTH-WEST OF ENGLAND.—PARTNERSHIP.—A two-thirds or three-fifths share is offered in a well-estab. PRACTICE, in particularly attractive district near two good towns. Gross cash receipts for last 12 months over £2,500. Panel of 1,500. Fees from 2/6 to 10/6. Not much midwifery. Exceptionally nice house, specially built, with all modern conveniences, 3 reception, 6 bedrooms, beautiful garden. Price for freehold £3,000, half on mortgage. Premium 2 years' purchase. Hunting, fishing, etc., and good schools within reach. Up-to-date Hospital, and excellent surgical scope.
8. KENT.—WITHIN THIRTY MILES OF LONDON.—PARTNERSHIP.—A one-third share (with increase to one-half later) is offered in a good mixed-class Practice, having large scope and very good surgical prospects. Gross cash receipts for last twelve months over £2,000. Panel of 745. Fees 3/6 to 21/-. Good house, with 3 reception, 5 bedrooms, etc. Can be rented on lease at £100 p.a. Sport of all kinds and good schools. Premium 2 years' purchase. A preliminary Assistantship of three months will be entertained.
9. SUSSEX.—PARTNERSHIP.—A one-third to two-fifths share is offered in an old-established Practice in desirable residential district, near sea. Gross cash receipts for last 12 months approximately £5,700. Panel of 1,700, and appts worth about £200 p.a. Fees 3/6 to 21/-. A preliminary Assistantship is offered at a salary of £500 p.a., plus unfurnished house.
10. LONDON.—OUTLYING RESIDENTIAL SUBURB.—PARTNERSHIP.—A one-third share, to commence, is offered in a good middle-class Practice, having large scope. Cash receipts for last 12 months about £2,700, including panel of 1,500. Suitable house can be purchased for £1,750, part on mortgage. Premium 2 years' purchase.
11. DEATH VACANCY.—NORTH WALES COAST.—Well-established PRACTICE, in pleasant town, producing £1,200 p.a., including panel of 794, and appts. worth about £200 p.a Visits from 5/- to 2 gns. Suitable house can be rented at £46 p.a. Efficient locum in charge. Premium £1,200, to include all drugs, surgery furniture and fittings, etc., payable £500 down and balance by instalments.
12. NORTH WALES.—Very old-established good mixed-class PRACTICE, averaging £880 p.a., including panel of 433. Fees 2/6 to 10/6, medicine extra. Suitable house, with 2 reception, 6 bedrooms, etc. Can be rented on lease at £50 p.a. Good sport. Premium £1,200, part down and balance by instalments. Ill health reason for sale.
13. WEST OF ENGLAND.—LARGE TOWN.—Well-established PRACTICE, producing nearly £900 p.a., including panel of over 1,300. Suitable house, in excellent position. Price £700, or can be rented at £60 p.a. Premium £1,450. Good scope for increase.
14. SOUTH-WEST OF ENGLAND.—FAVOURITE COAST TOWN.—Old-established good middle-class non-dispensing PRACTICE, averaging £2,100 p.a.- Selected panel of 700. Very good appointments worth about £400 p.a. Fees 5/- to 21/-. Midwifery from 5 gns. About 10 cases yearly. House contains 2 reception, 4 bedrooms, etc., waiting, and consulting rooms. Freehold can be bought, or other suitable houses available. Good hospital in the town, and excellent scope for surgery. Premium 2 years' purchase.
15. ESSEX.—COAST-TOWN.—Increasing PRACTICE, situated in good-residential district, and producing over £1,000 p.a., including selected panel of 100, and good appts. worth about £210 p.a. Large modern house, with beautiful garden; can be rented or bought. Premium £1,150.
16. DEATH VACANCY.—ESSEX.—COAST TOWN.—Small PRACTICE, offering large scope for energetic worker. Receipts for the past 12 months £220, including panel of 54. Visits 3/6 to 5/-, medicine extra. Suitable house, with 2 reception, 3 bedrooms, etc., and professional rooms. Garden. Garage. Price freehold £1,100, or can be rented on lease at £75 p.a. Very good sport and schools. Offers invited.
17. LONDON, S.W.—Good middle-class PRACTICE offering considerable scope, and producing for the past 12 months over £670, including panel of nearly 400. Fees from 2/6. Midwifery 3 gns. (about 30 cases yearly). Suitable house, with dining room, consulting room and dispensary, 3 bedrooms, sitting room, etc. Price for leasehold (94 years to run) £1,200, part on mortgage. Premium £1,050.
18. MIDLANDS.—PARTNERSHIP.—A one-third share is offered in a very sound middle and working-class Practice, held by the senior partner for 35 years. Average gross cash receipts for the past three years nearly £3,000. Panel of over 1,600. Fees 3/6 to 21/-. Midwifery from 3 gns. (about 60 cases). Suitable house available on rental, with 2 reception, 3 bedrooms, etc. Small garden. Garage. Sport of all kinds, and very good schools within reach. Prem. 2 years' pur.
19. MID-WALES.—Agricultural District.—Mixed-class PRACTICE, producing about £880 p.a., including small panel of 150. Fees 3/6 to 21/-. Small house, with 2 reception, 3 bedrooms, etc. Price £550. Fishing, shooting, and other sport. Premium 1 year's purchase.
20. WOMAN DOCTOR'S PRACTICE.—YORKS.—LARGE TOWN.—Established eight years, easily worked, and producing nearly £700 p.a. Panel of 500. Fees 5/- to 7/6. Midwifery 3 to 5 gns. Compact house, with 2 sitting, 2 bedrooms, 4 attics, etc. Garden. Garage. Rent on lease £42 10s. p.a. Prem. 1½ years' purchase, or near offer.
21. CHESHIRE.—NEAR COAST.—Old-established middle and working-class PRACTICE, averaging for the past three years over £1,300. Panel of 550. Fees from 3/6. Good house, with 3 reception, 7 bed. rooms, etc. Price for freehold £1,200, part on mortgage. Premium 2 years' purchase.
22. WITHIN FOUR MILES OF THE BANK.—Old-established working-class PRACTICE, producing for the last 12 months £2,300, including panel of over 2,800. Appts. worth about £160. Visits from 2/6. Low expenses. Suitable house can be rented or bought. Surgery premises on rental. Premium £4,000 cash.
23. SOUTH AFRICA.—Within 100 miles of East London.—Increasing PRACTICE, in very pretty Township near sea coast, producing last financial year £1,066. Practically all fees cash. Climate excellent. No night work and little or no visiting. Living cheap. Bungalow residence in 3/4 acre of productive garden. Premium for Practice and house £1,155. Sport of all kinds.
24. BORDERS OF BERKS AND HANTS.—In a delightful sporting and agricultural district, within reach of market town, an old established mixed-class PRACTICE averaging about £850 p.a., including panel over 400. Visits 5/- to 10/6, medicine extra. House containing 3 sitting, 7 bedrooms, bathroom, etc. Large garden. Garage. Rent £50 p.a. on lease. Premium £1,100.
25. MANCHESTER.—Semi-residential Suburb.—Very old-established non-dispensing mainly middle-class PRACTICE, averaging £2,500 p.a., including small selected panel of 440, which latter is capable of extension. Visits 5/- upwards. Only about 20 cases of midwifery from 5 gns. Well-situated house, with good accommodation. Price (freehold) £1,600. Premium £3,750.
26. NORTH DEVON & CORNWALL BORDERS.—Very old-established opposed Country PRACTICE, in beautiful district near coast, the receipts average just over £1,100 p.a., including appt. and panel of 330. Suitable house available. Premium £1,600, to include drugs, etc. Hunting, golf, fishing, etc.
27. NORTH MIDLANDS.—WITHIN 3 MILES OF FAVOURITE TOWN.—Old-established and good middle-class PRACTICE, offering large scope. Cash receipts for last 12 months £1,332, including panel of 1,000. Fees from 3/6. Mid. from 2 gns. Exceptionally nice house in about 4 acres of ground, with tennis lawn, fruit and vegetable gardens, etc., containing 3 reception, 6 bedrooms, etc. Freehold for sale. Premium 1½ years' purchase.
28. SOUTH OF ENGLAND. Pleasant Town near Coast.—Very old-established middle and upper-class PRACTICE. Cash receipts nearly £1,750 p.a., including panel of 500. Visits 3/6 to 21/-. little midwifery. House, including consulting room, waiting and dispensary, in well-situated part of town. Price, freehold £1, and dispensary, in well-situated part of town. Price, freehold £1,
29. LINCS. — PLEASANT MARKET TOWN. — PARTNERSHIP. — Average share, with possible succession in two years' time. Average for past three years £1,900, including appointments and panel of ducing £500. Advice and medicine 3/- upwards; visits from Very few midwiferies from 2 to 3 guineas. Large house and garage. Price freehold only £1,200. Sport of all kinds. excellent schools for boys and girls. Premium 2 years' purchase, payable £1,000 down, remainder by arrangement.

Full Schedule of Terms and Conditions will be forwarded on application.

Printed and published by the British Medical Association, at their Office, Tavistock Square, in the Parish of St. Pancras, in the County of London.

CAESAREAN TWINS

An interesting case has been recently recorded of a mother suffering from extreme pelvic contraction following tuberculous disease of the spine. Cæsarean section was performed at the 34th week, and two live children were delivered.

The mother was unable to feed the twins and they were brought up on Full Cream Cow & Gate. Their progress was uninterrupted, and at the age of 2½ years they each weigh 28 lb.

This report is a remarkable testimonial to the value of Cow & Gate, which adequately replaced breast feeding for a mother too delicate to nurse the two children; the twins, moreover, suffered from the disadvantage of prematurity.

Reported in the "British Medical Journal," August 1st, 1931

Saved by

"Cow & Gate made safe and natural for baby"

The makers will gladly supply samples for clinical test and any further information required. Members of the Medical and Nursing professions are also reminded that the Cow & Gate Laboratories are always at their disposal for experimental work in connection with Milk Foods, and the makers will be delighted to arrange visits to their factories in the West of England at any time.

THE BEST MILK FOR BABIES WHEN NATURAL FEEDING FAILS

The Treatment of Scarlet Fever

THE Streptococcus Antitoxin (Scarlatina) issued by Parke, Davis & Co., is prepared in their Biological Laboratories by methods approved by the Scarlet Fever Committee. The potency is determined by a skin test on the susceptible human subject.

It is a refined globulin serum, concentrated by methods which eliminate a large proportion of undesirable protein constituents.

The exceedingly high potency of the Parke-Davis product makes it an outstanding preparation of its kind.

In the treatment of scarlet fever the injection of this antitoxin is capable of effecting a rapid reduction of temperature and pulse rate. When the antitoxin is administered within the first three or four days of the disease the effects are said to be dramatic. Often it has been possible to reduce the period of isolation for serum-treated patients to as little as three weeks.

The antitoxin is also valuable for conferring passive immunity on contacts. It may also be employed for the Schultz Charlton rash-fading diagnostic reaction.

STREPTOCOCCUS ANTITOXIN (Scarlatina) P., D. & Co.

Full particulars will be sent on request.

Ergot superseded by

TRADE 'ERNUTIN' MARK

A clear solution presenting Ergotoxine (the specific active principle of the official Ergot), together with 'Ergamine' and 'Tyramine,' in definite amount and in a state of chemical purity.

Used with consistent success in obstetrical practice to induce contraction of the uterus after labour.

Ergotoxine Ethanesulphonate, used in the preparation of 'ERNUTIN,' is the most stable salt of Ergotoxine and was introduced originally by BURROUGHS WELLCOME & Co.

'ERNUTIN' (Oral)
Contains 0·033 per cent. of Ergotoxine Ethanesulphonate
Bottles of 30 c.c., 4 fl. oz., and 16 fl. ozs. at 2/6, 7/6 and 25/- each, respectively

'HYPOLOID' 'ERNUTIN'
for [illegible]
Contains 0·1 per cent. of Ergotoxine Ethanesulphonate
Boxes of six hermetically-sealed rectal cones of 0·5 c.c. (approx. one-half of standard solution) at 2/4 per box

Prices quoted are those in London to the Medical Profession

The effective treatment

in

PNEUMONIA—INFLUENZA
CORYZA

is provided by

EDWENIL

A Polyvalent Antibacterial Agent.

A typical pneumonia report states:

"Male adult, admitted to hospital on the second day of illness, suffering from double lobar pneumonia. His condition appeared hopeless. He was very deeply cyanosed, pulse 140, respiration 48, temperature 103·2°.

"2 c.c. of Edwenil were given, followed by a fall in temperature to 99° in 12 hours. A second dose of 2 c.c. was given. Temperature rose to 102·4° and fell again in another 12 hours.

"This cycle was repeated and temperature reached normal on the 6th day. Six hours after the first injection, it was obvious that he was more comfortable. The cyanosis began to subside on the second day. From that time improvement was rapid and uneventful."

Edwenil is available in 12½ c.c. and 25 c.c. bottles, and in boxes of three and twelve 2 c.c. ampoules.

Just Issued

WECHSLER'S Clinical Neurology

New (2nd) Edition

This book is based largely upon the clinical and teaching experience of the author—it is an individual approach to neurology, and is, therefore, the more practical and usable. Since the appearance of the first edition four years ago, many advances have been made which have necessitated a most thorough revision of the entire text. Besides bringing the previous edition up to date, Dr. Wechsler has included several neurological syndromes which were omitted from the first edition. The illustrations have also been revised, a number of new ones added, and others of greater clinical value substituted for some appearing in the first edition.

"Dr Wechsler's book is readable and remarkably wide in its range . . . it serves its purpose well, and for the student and practitioner it appears to constitute a useful compendium of practical neurological medicine"—LANCET (Review of first edition)

By ISRAEL S WECHSLER, M D, Professor of Clinical Neurology, Columbia University, New York. Octavo volume of 759 pages, illustrated. Second Edition, Revised. Cloth, 35- net

Da Costa's Modern Surgery

NEW (10th) EDITION

"Wide and discriminate reading, evincing the most ample knowledge of the literature of his subject, a scrupulous fairness in appraising other men's ideas and methods, a transparent honesty and complete absence of dogmatism, are the most attractive features of this book"—DUBLIN JOURNAL OF MEDICAL SCIENCE

By J. CHALMERS DA COSTA, M D, Professor of Surgery, Jefferson Medical College, Philadelphia. Tenth Edition, Just Issued. Octavo of 1,404 pages, with 1,050 illustrations, some in colours. Cloth, 45s net.

Boyd's Surgical Pathology

NEW (2nd) EDITION

"Accurate, clear, and well illustrated . . . An unusual but commendable feature for a book on pathology is the summary of symptoms which accompanies many descriptions, thus providing a link between the laboratory and the clinical sides . . . The book is well described by Dr W J Mayo as a sincere attempt to place pathology before the student and practitioner from the practical standpoint"—BRITISH MEDICAL JOURNAL

By WILLIAM BOYD, M D, M R C P Ed, F R S Can, Professor of Pathology, University of Manitoba. Octavo of 933 pages, with 476 illustrations and 15 coloured plates. New (2nd) Edition. Cloth, 42s net.

Howell's Physiology

NEW (11th) EDITION

"It is an encouraging sign of the times that a text-book so remote from any approach to the cram-book should have gained so much popularity with the medical student . . . The author has succeeded in making his subject-matter interesting and in many parts fascinating—an art deplorably rare in physiological writings. The book may be respectfully commended"—EDINBURGH MEDICAL JOURNAL

By WILLIAM H HOWELL, M D, Ph D, Professor of Physiology, Johns Hopkins University, Baltimore. Octavo of 1,099 pages, illustrated. Eleventh Edition. Cloth, 30- net

MacCallum's Pathology

FOURTH EDITION

No doubt this book has often been taken down from the laboratory shelf to verify some small point which has to be explained immediately the information sought has been obtained. It is apt to beguile the reader, entering first a corner and then going through it, as it teaches ideas rather than facts"—BRITISH MEDICAL JOURNAL

By W G MacCALLUM, M D, Professor of Pathology and Bacteriology, Johns Hopkins University. Octavo of 1,177 pages, 603 original illustrations, 59 in colours. Fourth Edition. Cloth 50- net

W. B. SAUNDERS COMPANY Ltd., 9, Henrietta Street, LONDON, W.C.2

British Medical Association.

MEDICAL CHARITIES.

A British Medical Appeal.

These great Charities have been running for nearly a Century.
They were created and kept going only by the labour and devotion of our predecessors in Medicine.
They deserve support not only on this account but more from the fact that there is a vast amount of poverty and privation, the wreckage of the "dangerous trade" in which we are engaged.
They give inadequate assistance to over 1,200 persons every year—doctors, their widows and dependants.
It is inadequate because they have not enough money.
They have not enough money because so few subscribe regularly to our *Funds.*
There are about 27,000 members of the B.M.A. in the British Isles.
Of these less than 7,000 subscribe regularly.

This is not good enough.

The Teachers look after their own people.
The Commercial Travellers look after their own people.
The Licensed Victuallers look after their own people.
Shall the doctors be less generous than they
If every member would give to us we should easily have another £20,000 a year, and then we could do something.

Will you help us?

Five Shillings would be welcomed. A guinea is quite usual. Sometimes we get more. Rather over a guinea is the average subscription.
Anyhow, give us something when you pay your subscription, and remember—
That there are over 1,200 depending upon the medical charities;
That still more need your help, and
That you, fortunately, are not one of them!

J. & A. CHURCHILL

88th Annual Issue. 2,400 pages. 55,480 names. 36s.

THE MEDICAL DIRECTORY, 1932

Including a Medical Report on British Spas and Seaside Resorts. Edited by R. FORTESCUE FOX, M.D.

"... every practitioner who keeps up to date, can scarcely afford to be without a copy of this work."—THE LANCET, Dec 12th, 1931.
"... No reference book is consulted so often in this office as 'The Medical Directory,' and it would be ungrateful to let a new edition appear without testifying again to its value."—B.M.J., Dec 12th, 1931.

DISEASES OF THE HEART

THEIR DIAGNOSIS, PROGNOSIS, AND TREATMENT BY MODERN METHODS.

With chapters on the Ink Polygraph, Clinical Electro-Cardiography, X-Ray Examination, and Anaesthesia in Relation to Cardio-Vascular Affections.

By FREDERICK W. PRICE, M.D., F.R.S.(Edin.),

Senior Physician to the National Hospital for Diseases of the Heart, Consulting Physician to the Royal Northern Hospital, London

Demy 8vo Pp 534 With 249 text figures, including 32 sphygmograms 92 polygraphic tracings, and 87 electro-cardiograms

NEW SECOND EDITION, 21s. net.

"By great care and by the use of an amazing amount of material, he has accomplished what many readers have been waiting for, giving us a complete account of the diagnosis, prognosis, and treatment of heart diseases by modern methods in association with all the invaluable teaching bequeathed to us by the older masters of clinical observations."—LANCET.

The most valuable and comprehensive guide to the study of Cardiology with which we are acquainted."—NEW YORK MEDICAL JOURNAL AND RECORD.

We think that most of our readers engaged in general practice will find this work extremely useful."—THE JOURNAL OF CLINICAL RESEARCH.

In our opinion the book is indisputably the most authoritative contribution to cardiology of our time."—FRANCO-BRITISH MEDICAL REVIEW.

"A book which we believe is destined to remain the standard work on Cardiology for many years to come."—AMERICAN MEDICINE.

"The second edition of this popular work on heart disease bears evidence of thorough revision, while the essentially clinical standpoint of the writer is maintained."—EDINBURGH MEDICAL JOURNAL.

"It may be said at once that the book adequately fulfils the purpose it has in view, and is a perfectly sound, lucid, and reliable guide."—NEWCASTLE MEDICAL JOURNAL.

"Well written, concise, and complete, containing a wealth of practical information. Obviously based upon the author's own experience and investigative work."—SURGERY, GYNECOLOGY, AND OBSTETRICS (Official Journal of the American College of Surgeons).

"Dr. Price is to be congratulated again on the reappearance in its second edition of his distinguished contribution to the increasingly important subject of Cardiology."—THE CANADIAN JOURNAL OF MEDICINE AND SURGERY.

OXFORD UNIVERSITY PRESS, Amen House, Warwick Square, London, E.C.4.

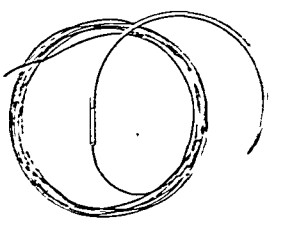
London Hospital Eyeless Needles

WITH L.H. CATGUT



The London Hospital Eyeless Needles have been specially designed to avoid the doubling of the suture necessary in using needles with pierced eyes. They are fitted with tubular ends into which the sutures are firmly fixed, thus enabling the needles to be used with single strands. These needles are finely ground, sharp pointed and packed sterile in tubes for immediate use. Special precautions are taken to avoid any rusting of the needle after it has been packed.

TO COUNTER ACIDOSIS

As SALVITAE contains 59% of Potassii et Sodii Citro-Tartras and 30% of Sodii Sulphas it is of great value both in maintaining health and in the treatment of disease, through eliminating deleterious nitrogenous products and favourably influencing circulation, glandular secretions, peristalsis, and metabolism.

The fruit acids of SALVITAE are converted in the system into potentially basic alkaline carbonates, thus enabling the blood to keep the uric acid compounds in solution, and facilitate their removal.

WHOOPING COUGH

The best practice in the treatment of Whooping cough recognizes the importance of keeping the patient out of doors as much as possible. The food should be easily digestible, nourishing, and given a little at frequent intervals.
There are no specifics for this disease. In very young children drugs are administered with difficulty and are of uncertain effect.
Vaporized Cresolene at night will be found a simple and effective means of preventing the paroxysms at that time, thus tending to preserve the strength of the patient, avoid complications, and hasten convalescence.

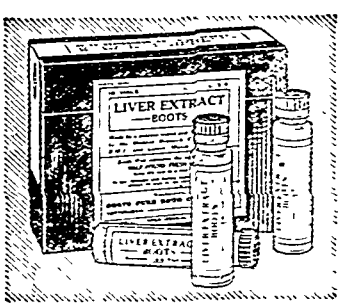
THE VITAMIN B_1 CONTENT OF LIVER EXTRACT

"The results suggest that those liver extracts which are rich in B_1 as well as in B_2 should be included in the list of medicaments available for use in cases in which administration of the vitamin B complex is indicated. Clinical evidence can indeed be adduced that such extracts are of practical value as general tonics, a fact which may be partly attributable to their vitamin content."



Extract from "The Lancet," June 27th, 1931, pp. 1423 and 1424.

LIVER EXTRACT (BOOTS) has been proved to be rich in both Vitamin B_1 and Vitamin B_2.

OVALTINE

FOR THE GROWING CHILD

"Ovaltine" is indicated as a means of promoting normal growth and development when the weight of the child under observation is less than that which statistics show a child of the same height should weigh.

The physician has only to consider the composition and properties of the product to recognize how suitable it is as a building and reconstructive nutrient.

"Ovaltine" is a concentrated extraction of malt, milk, and eggs in the form of golden brown granules. For tissue growth or repair it provides proteins, mineral constituents, adequate energy value, and the Accessory Growth Factors or Vitamins in correct nutritive ratio.

Children love the deliciousness of "Ovaltine" and thrive remarkably well upon this complete food. It is of unsurpassable value as a meal-time beverage in place of tea, coffee, cocoa, or other beverages.

A liberal supply for clinical trial sent free on request.

A. WANDER, Ltd., 184, Queen's Gate, S.W.7.

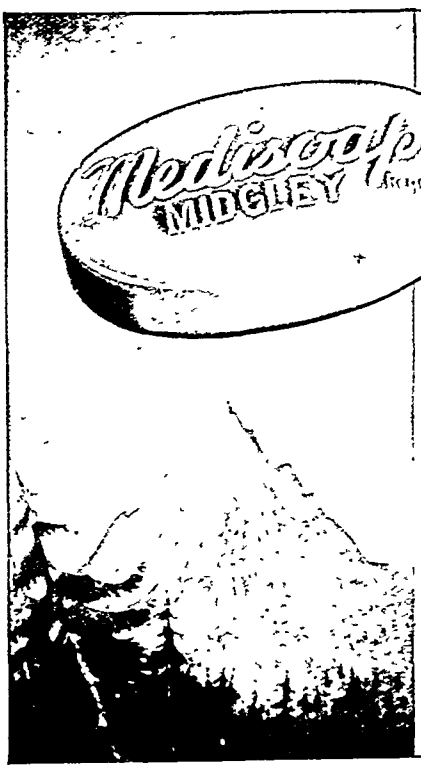
AN ESSENTIAL INCLUSION IN EVERY MIDWIFERY AND ANAESTHETIC BAG

CO_2 IN RESUSCITATION.

"I B R," in the "British Medical Journal," Nov. 7, 1931, page 878, writes —



"Apropos CO_2 as a respiratory stimulant, at a recent confinement, as the result of premedication of the mother, of instrumental delivery, or of some cause unknown, the child was born in a condition of partial asphyxia. Half an hour's effort to restore respiration proved ineffective, beyond producing a spasmodic inspiratory gasp at intervals. The baby appeared to have definitely decided not to remain. It then occurred to me to try the "Sparklet" apparatus, or, I should rather say, contrivance, which one carries in the anaesthetic bag. The result of discharging a little CO_2 in front of the baby's mouth at the moment of its making a rare inspiratory effort was instant and amazingly effective. The rhythm was started, and in a few minutes all anxiety had vanished. Admittedly there is nothing startlingly new in this phenomenon. I feel, however, that I am justified in relating the experience from the conviction that the average practitioner is unaware that he has to his hand a simple inexpensive little CO_2 container, suggested by a Manchester anaesthetist and manufactured by the "Sparklet" people. I now feel it should have a place in every midwifery bag, and that it will save many an infant life."

Local Anæsthesia in Surgical Practice

PULMONARY ABSCESS (Rib Resection)

Typical Case

C. R., female, aged 19 years, pregnant.

Diagnosis: Pulmonary abscess.

Operation: Costectomy; drainage and Beck's plastic.

Anaesthesia: Local infiltration and paravertebral intercostal block.

Operation: A rib resection was made under Local Anaesthesia, and after evacuating the cavity a subdermal infiltration was made outlining the flaps, which were dissected up and turned into the cavity. The patient showed no reaction from this operation. Twelve days later she went through a normal labour, giving birth to a healthy male child, and in three months the cavity was completely lined with healthy skin. Six months later the cavity was completely obliterated.

—EXTRACT from PRACTICAL LOCAL ANAESTHESIA (Farr).

(Full technique of this and one hundred other operations under Local Anaesthesia will be found in the above work, published by Henry Kimpton, 263, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANAESTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify "Novocain" for your next operation.

Does not contain Cocaine, and does not come under the Dangerous Drugs Act.

BOVRIL is an ideal stimulant nutrient

IRON AND ARSENIC "STERULES"

IN ANAEMIC CONDITIONS.

This combination has been before the Profession for many years, and we continue to receive favourable reports on its successful use.

Supplied in two strengths.

No. 1 Sterules. 15 m. (1 c.cm.) each containing 0,025 gm. (⅜ gr.) of Soluble Iron Arsenate, equivalent to ½ mgr. Arsenious Acid.

No. 2 Sterules. 15 m. (1 c.cm.) = 1 mgr. Arsenious Acid.

Boxes of 10, either strength, 3/-.

W. MARTINDALE (MANUFACTURING CHEMIST), 12, New Cavendish Street, London, W.1.

Telegraphic Address: "MARTINDALE, CHEMIST, LONDON."

Telephone Nos: LANGHAM 2441.

The confidence of the MEDICAL PROFESSION

Benger's Food has gained its unique position not by extravagant or sensational claims but by the constant recommendation of Medical Practitioners.

Benger's Food is scientifically prepared to adjust fresh cows' milk, diluted or undiluted, to suit the individual requirement of the patient. In this respect it is distinct from any other food obtainable.

Benger's Food is largely used as a routine treatment in all cases of impaired digestion. The following comments, recently made by Doctors, indicate some specific conditions in which the Medical Profession prescribes Benger's Food.

DYSPEPSIA.

"routine food in all cases of dyspepsia and disordered digestion."

"used for invalids and all gastric cases."

INFLUENZA.

"very largely used for Influenza in all its forms."

CANCER.

"invaluable for cancer of the throat."

"cancer of the stomach—doing well on Benger's Food."

THE AGED.

"very beneficial for man of greatly advanced years."

"invariably used for invalids and aged persons."

BENGER'S FOOD, LTD., MANCHESTER.

WESTERN TOWER OF A CHARACTERISTIC SAXON CHURCH ERECTED BY THE PIONEER TEUTONIC ARCHITECTS IN ENGLAND.—

Church-building in England of Teutonic times began about A.D. 600 and continued down to the Norman Conquest. In the earliest period there was little that was Teutonic in the architecture of combined Roman and Keltic elements; to it are usually assigned the churches of St. Martin and St. Pancras at Canterbury, with others at Rochester, Lyminge, Reculver, Brixworth, Ripon and Hexham (the crypts), Escomb, Monkwearmouth, Jarrow and Bradford-on-Avon. Later, at the beginning of the eighth century, native work was evolved and introduced by architects who thus contributed to the formation of the mediæval styles: among them Wilfrid of Hexham stands out. The tower of Earl's Barton church, coming still later, well exhibits some of these new features. In it is illustrated the characteristic Saxon treatment of the corners by long and short quoins. The pilaster strips between the string courses form another Saxon peculiarity, as does also the belfry opening cut through the whole thickness of the wall. Other Saxon features are double-splayed lights and strip work round openings.

THE 6 REQUIREMENTS OF THE PERFECT MOUTHWASH & GARGLE

★ Requirement No. 3

Odol is peculiarly suited to the needs of the oral cavity in that while it is perfectly harmless, it is an effective antiseptic. When diluted with water, Odol gives a permanent emulsion that yields up its antiseptic only in consequence of an absorption by the whole surface of the oral cavity. The very finely separated drops of oil of the Odol antiseptic are held fast by the mucous membrane, until broken up into their effective components. Odol has a Rideal Walker co-efficient of 0.6, and exercises an inhibitory effect which lasts for hours.

The Six Requirements—

1. It must be absolutely harmless.
2. It must be absolutely non-irritant to the mucous membrane of the mouth.
3. ☆ It must be definitely antiseptic.
4. It must be neutral in reaction.
5. It must be deodorising and refreshing.
6. It must be agreeable to the taste.

—are all fulfilled by

Odol

Samples and literature will be gladly sent to any member of the Medical Profession in the British Isles or the Irish Free State on request to Cranbur Ltd. of Norwich.

Observations
ON
OCULAR PALSIES*
BY
GORDON HOLMES, M.D., F.R.C.P.
PHYSICIAN, CHARING CROSS HOSPITAL AND NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC

We are accustomed in dealing with loss of the power of movement of any part of the body to distinguish those varieties due to structural lesions of, or functional disturbances in, the upper motor neurones which carry impulses from higher centres to the motor nuclei and their nerves, and those the result of lesions of the nuclei and nerves which innervate the muscles directly. The latter are the lower motor neurones or the final common paths, for by them only can nervous impulses reach the muscles.

This distinction of two types of paralysis can be profitably applied to the ocular movements, too, though here, owing to the inaccessibility of the muscles to direct examination, some of the characteristic features of each type of paralysis are not readily recognizable; we cannot, for instance, by the ordinary means of examination detect wasting of the ocular muscles, or test easily their electrical excitability, but the essential differences are obvious, for in lesions of the upper motor neurones movements as such are lost, and sometimes those that normally are excited by certain impulses only, while in disease of the lower motor neurones the muscles themselves are paralysed and react to no nervous message. This can readily be seen by contrasting a left internal rectus paralysis with a palsy of conjugate movement of the eyes to the right, for in the former the left eye is not adducted whether the patient attempts to look to the right or to converge, while in the latter case the left eye comes into the inner canthus as readily and fully as the right when the patient tries to converge; the internal rectus muscle is therefore not paralysed, but fails to contract in a certain movement only, that is, looking to the right. This corresponds to the condition we so frequently meet in an upper neurone paralysis of the limbs, in which no movements may occur in response to voluntary effort, but they can be excited reflexly or synkinetically.

Owing partly to the necessity of an extremely accurate adjustment of the movements of the two eyes in response to numerous stimuli, and partly, perhaps, to the considerable distance apart of the nuclei from which the ocular nerves arise, the nervous mechanisms which control the ocular movements are more complicated, and according to the part of it which is involved two types of supranuclear palsy can be distinguished—the so-called conjugate or associated paralysis in which no movement of the eyes in one or more directions can be obtained by any means, and the true supranuclear palsies in which movement of the eyes in certain directions is lost to certain stimuli only, but can be affected by others.

Whether the regulation and co-ordination of the ocular movements depend on special centres in the brain stem which receive and distribute to the motor cells all impulses that bring about contraction and relaxation of all the muscles concerned in the movement, or whether the distribution of the impulses is determined merely by the anatomical arrangement of the fibres that conduct them, need not be discussed here. There are certainly arguments in favour of each hypothesis. We can, however, divide ocular palsies into three main and distinct classes:

1. *Paralysis of the ocular muscles*, due to disease of their motor nerves or nuclei.

2. *Conjugate palsies*, in which the movements of both eyes in one or more directions are lost to all adequate stimuli.

3. *Supranuclear palsies*, in which movements of the eyes can be excited by certain stimuli only, but not by other impulses which elicit them under normal conditions.

Paralysis of the Ocular Muscles

These, owing to their frequency and their importance in general medicine as well as in ophthalmology, deserve first consideration. The muscles which are affected depend on which nuclei or nerves are involved by the lesion. The essential feature is that the muscle is weak or paralysed in all movements in which it may be concerned. As its palsy leads to loss of parallelism in the visual axes, strabismus results, and if the faculty of projection of the image formed on the retina of the squinting eye is preserved, diplopia occurs.

The wide distribution of the ocular nuclei in the brain-stem, and the long and exposed courses of the ocular nerves on the base of the skull, are the chief reasons why they are so frequently damaged by intracranial disease. The nerves are particularly liable to suffer when the membranes on the base of the brain are involved. According to the anatomical site of the lesion these ocular palsies may be divided into: (a) nuclear palsies, in which the nucleus is involved, (b) stem palsies, due to interruption of the motor fibres as they pass through the brain stem, and (c) root palsies, in which the extra-medullary portions of the nerves are affected. It is not, however, always possible to distinguish clinically to which of these three types any case belongs.

Nuclear Palsies

These are most commonly due to local lesions of an inflammatory, vascular, or neoplastic nature involving one or more of the ocular nuclei. It may be a haemorrhage or a softening due to vascular occlusion, or to a tumour growing in or compressing the brain stem. The mode of onset and development of the palsy, and more particularly the other signs of injury of the nervous system which are almost invariably associated with these lesions, usually make it possible to distinguish them. Isolated ocular palsies following on an injury to the head are, however, often not accompanied by other symptoms; in many of these the nerve is torn or bruised in the vicinity of a fracture through the base of the skull, or compressed by a meningeal haemorrhage, but small haemorrhages into the central grey matter of the brain stem not infrequently involve the ocular nuclei, especially that of the third nerve. The explanation of this is probably that the momentum of the blow sets up a wave in the cerebro-spinal fluid of the third ventricle, which breaks with its greatest force against the grey matter around the anterior end of the aqueduct of Sylvius, where the nucleus of the third nerve lies. In such cases the ocular palsy may be the only symptom.

Inflammatory lesions are often more difficult to recognize with certainty. Paralysis of one or more ocular muscles is sometimes due to acute poliomyelitis, and unless it occurs during an epidemic may be difficult to diagnose. Encephalitis lethargica has been, since the recent outbreak of this disease, such a common and well-recognized cause that further reference to it is scarcely necessary, but as during the last few years few, if any, acute cases of this form of encephalitis have occurred in England, at least, a warning may be entered against using this diagnosis as

* Read in opening a discussion in the Section of Ophthalmology at the Annual Meeting of the British Medical Association, Eastbourne, 1931.

a convenient explanation of acute ocular palsies. We still, however, meet occasionally paralysis of the ocular muscles recurring or appearing for the first time in chronic cases of this disease. Acute bilateral ophthalmoplegia due to inflammatory nuclear lesions is an important, though not a common, type. Wernicke originally described it in cases of chronic alcoholism as acute superior haemorrhagic polioencephalitis, since haemorrhages into the grey matter are the most striking anatomical change, but in two cases which I examined there was a considerable inflammatory reaction as well as small extravasations in the ocular nuclei. It has been described in other intoxications, as in poisoning by lead, sulphurous acid, ergot, phosphorus, and particularly in botulism. In most of these the intrinsic as well as the external ocular muscles are affected, but in food poisoning there may be an ophthalmoplegia interna only.

In contrast to these acute nuclear affections, there is a group of cases of chronic nuclear ophthalmoplegia in which a progressive degeneration of the nerve cells is assumed to be the essential lesion, but few of these cases have been examined anatomically. It generally develops in middle life, and in some of the recorded cases, and in two of my own, there was a definite familial or hereditary tendency. The course is slowly progressive: at first a few muscles only, and frequently the levatores palpebrarum, are paretic, but all the external muscles are gradually involved, but in many cases the intrinsic muscles escape.

Stem Palsies

Stem palsies, due to lesions of the fibres of the roots as they pass through the brain stem, can be usually recognized by the accompanying symptoms produced by involvement of other nervous structures by the causal lesion. In these cases one often meets the various types of crossed hemiplegia, in which there are ocular palsies on the one side, and a hemiplegia, a hemianaesthesia, or disturbances of co-ordination on the other, as in the syndromes described by Benedikt, Weber, Gubler, Millard and others. The chief clinical interest of this type is that it includes the ocular palsies of disseminated sclerosis, for in this disease the root fibres are involved before they leave the brain stem, though possibly in some cases the palsies may be the result of nuclear lesions.

Root Palsies

There can be no doubt, however, that in the great majority of ocular palsies the lesion involves the extramedullary portions of the roots in their intracranial course. It is here the fibres are damaged in acute and chronic meningitis, in superficial or subarachnoid haemorrhage, in fractures of the base of the skull, by tumours, and by a toxic or infective neuritis.

Lesions of the roots are also responsible for most of the ocular palsies met with so frequently in cerebral syphilis, and probably for the majority of those occurring in tabes dorsalis, though in this disease a primary degeneration of the motor cells, especially of those of the third nerve, has been described. It is well known that while in some cases the tabetic palsies recover under specific treatment, in others they are permanent; the first group may be due to compression or gummatous infiltration of the roots as they pass through the membranes, the second to atrophy of the nuclear cells.

The other more important groups of root palsies are those due to infections or intoxications producing a degenerative or parenchymatous neuritis of the nerves; those the result of raised intracranial pressure; and those associated with cerebral arterio-sclerosis.

Ocular palsies are not infrequent in generalized peripheral neuritis, as in that due to alcohol and diphtheria in these there is no doubt the ocular nerves, like those of the limbs, suffer directly from the action of a circulating poison or toxin that produces disintegration of the myelin sheaths and other characteristic changes. Similar palsies, usually isolated and transient, have been described in many other infectious diseases, including influenza. They are not uncommon in diabetes, but their pathology in this disease has not been yet definitely established. Whether a true rheumatic paralysis of the ocular nerves exists is open to doubt; not infrequently signs of palsy of one or more of the ocular nerves, or even a complete ophthalmoplegia, follows exposure to cold without other cause being apparent, but the sheltered course of the nerves, far from the surface of the body, makes it improbable that cold can affect them directly. The more likely explanation is that cold merely lowers resistance to some infection or other pre-existing pathological condition. Finally, the palsy of the external rectus muscle, which occasionally follows the use of stovaine and similar drugs for spinal anaesthesia, deserves mention; it seems that the fibres of the sixth nerve are particularly vulnerable to the small amounts of these drugs which diffuse into the intracranial cavity.

An infective or interstitial neuritis of the nerves, apart from meningitis and syphilis, is rarer, but it is occasionally found in association with suppurative disease of the cranial sinuses. The most common form is the abducent palsy in otitis media, due probably, as Gradenigo suggests, to the infection spreading along the air cells and involving the nerve where it passes the apex of the petrous bone in its extradural course. In cases of ethmoiditis in which one of the ocular nerves, in my experience most frequently the third, is paralysed, the lesion is probably a similar infective neuritis. The ocular palsies which have been repeatedly observed in herpes, involving the trigeminal and upper cervical root areas, are probably due to direct infection and infiltration of the nerves.

Various ocular palsies are common in intracranial tumours and aneurysms; they may be due to direct compression of the nerve, as is likely to happen when the tumour lies near the base of the brain, or they may be caused indirectly by compression or by displacement of the brain. The external rectus palsy, which so frequently occurs in cerebral tumours, no matter what their locality may be, is due to displacement backwards of the brain stem and the consequent stretching of the nerve, which is held in position at its exit from the pons by the middle cerebellar artery around which it bends

Another [illegible] ocular palsies which is usually [illegible] opinion it is relatively common,

[illegible] nerves by an arterio-sclerotic

[illegible] motor nerves lie in close [illegible]

[illegible] base of the brain; the [illegible]

so close to [illegible] the middle cerebellar, and it is

may be compressed when this vessel is thick and tortuous.

the fourth nerve crosses the posterior cerebral, and the

third lies in the narrow space between the superior cerebellar and the posterior cerebral arteries as the latter

leave the basilar. Further, all three nerves run relatively

close to the internal carotid artery in the cavernous sinus.

It might be therefore expected that when any of these

arteries are dilated or tortuous they might press on one

of the nerves sufficiently to interfere with the conduction

of impulses through it. This occurs chiefly in elderly subjects with signs of cerebral arterio-sclerosis and raised intracranial

pressure. The palsy usually develops rapidly, is rarely

complete, and generally disappears within a few

if the patient is kept at complete rest and iodides or drugs that lower blood pressure are administered.

Ocular palsies associated with pain and sensory disturbances in the area of the ophthalmic division of the trigeminal nerve constitute the characteristic clinical picture produced by disease in the region of the sphenoidal fissure. A squint with diplopia may be the earliest symptom, but frequently the patient first complains of pain in the forehead and behind the eye. The order and the relative severity in which the nerves are involved naturally depend on the exact site of the lesion in the fissure, but usually a complete ophthalmoplegia results, and cutaneous sensation in the area of the ophthalmic nerve is lost or greatly diminished. A syphilitic periostitis is one of the most common causes of this syndrome, but it occurs also with tumours and inflammatory lesions in the region of the sphenoidal fissure. In many cases, however, the nature of the lesion cannot be determined. Except when the lesion is syphilitic and the patient can be treated early, the prognosis as regards recovery of the ocular movements is usually bad.

CONJUGATE OCULAR PALSIES

This is the term usually applied to loss of the power of movement of the two eyes in any direction, provided this is not due to the chance association of paralysis of the prime movers of each eye. It is characterized by the facts that the loss of movement develops equally and simultaneously in the two eyes and squint and diplopia consequently do not occur or are subsidiary features, and that though in attempting the movement the palsied muscles do not contract they may act normally in some other movement; the left internal rectus, for instance, may fail to move the eye inwards on attempting to look to the right, but functions normally on convergence. It is therefore a palsy of movement rather than of muscle.

The most common form is perhaps paralysis of the lateral movements of the eyes to the one side. This frequently results from disease in the lower and dorsal portion of the pons varolii in the region of the nucleus of the sixth nerve. When unilateral the patient is unable to look towards the side of the lesion. In such a case the internal rectus of the one eye and the external rectus of the other fail to contract, and as these muscles are innervated from two separate nuclei about 3 cm. apart, it is necessary to assume that they receive branches from the same fibres, or are connected by association fibres which distribute the same impulses to the cells of both. As in conjugate palsies the muscles fail to respond to all impulses, to those from the vestibular and other mechanisms in the brain stem and from subcortical centres, as well as to cortical messages, the first hypothesis necessitates the assumption of a very complicated arrangement of fibres. On other grounds, too, it seems more probable that conjugate lateral deviation depends on association fibres between the sixth and third nerve nuclei, and we know such exist in the dorsal longitudinal bundles. These tracts have undoubtedly an important part in the co-ordinated movements of the eyes. It is beyond doubt that the impulses which can effect conjugate lateral movements converge towards the region of the sixth nucleus, those from the forebrain passing by the nucleus of the third nerve in their downward course. From here part of them are shunted back to the nucleus of the opposite internal rectus along another path in the dorsal longitudinal bundles.

The exact position which a lesion must occupy to cause a conjugate palsy of lateral movement of the eyes to the same side has not been definitely determined; according to some it must involve the sixth nucleus, but it is more probable that the controlling mechanism lies, not in the abducens nucleus, but oral, and slightly ventral to it. It is here that all the paths conveying impulses for lateral movement to the same side converge, and a lesion in this position, therefore, abolishes reflex as well as voluntary deviation of the eyes in this direction. As this mechanism lies near the middle line of the brain stem, a single focus of disease often affects lateral movements to the two sides, but the patient can still deviate his eyes upwards and downwards, and converge normally.

Occasionally, a lesion involves the associational fibres connecting the sixth with the third nerve nucleus; then, on attempting to look to the same side, the ipsilateral eye deviates outwards, but the contralateral eye does not pass the middle line, though it rotates inwards in convergence.

The conjugate vertical movements may be similarly abolished, either together or separately, or convergence may at the same time be impossible. The exact positions lesions must occupy to produce these conjugate palsies of vertical movement have not been definitely ascertained; according to some authors upward and downward movements are lost when the anterior quadrigeminal bodies are injured, but others attribute these palsies to lesions in the tegmentum of the anterior part of the midbrain. There is, however, considerable evidence that the mechanism for elevation of the eyes lies more anteriorly than that for depression. As the power of convergence is frequently lost in association with palsy of downward deviation, we may assume that the nervous apparatus that control these two acts lie close together.

SUPRANUCLEAR OCULAR PALSIES

While in conjugate palsies no movement of the eyes in one or more directions can be obtained by any means, in the so-called supranuclear palsies the eyes fail to move in response to certain stimuli only. It is often assumed that the movements of our eyes are largely volitional or under control of our will, but these represent a small part only of the ocular motor activities; impulses which determine ocular postures and movements are constantly flowing in from the vestibular nuclei in the brain stem, from the lower visual and auditory centres in the midbrain, from the occipital cortex and from other sources. It happens not infrequently that movements in response to one or more sets of these impulses only are lost, while those excited by other impulses are preserved. In the most common type the patient is unable to deviate his eyes in one or more directions when he is ordered to do so or asked to look towards an object held in these directions, but these movements can be elicited by labyrinthine stimulation and other means. As a rule, when the power of voluntary movement is abolished the eyes can follow a slowly moving object which the patient has fixed, and if while he fixes his eyes on an object his head is moved actively or passively towards one side, his eyes still remain on the object—that is, they rotate in the direction opposite to the movement of his head. Following objects with the eyes, and the compensatory deviations that occur on movement of the head, are largely reflex acts, and dependent on other paths than those which effect voluntary movement. We must therefore assume that in the supranuclear palsies the lesions interrupt some of the afferent paths to the conjugate mechanisms, but leave the latter unaffected, and the available pathological evidence points to this conclusion.

Other forms of dissociation are occasionally met with, but, owing to rarity and their small clinical importance, further reference to them here is unnecessary.

THE IMPORTANCE OF HORMONES IN MENORRHAGIA *

BY

FRITZ LAQUER, M.D.

PROFESSOR OF PHYSIOLOGY, UNIVERSITY OF FRANKFORT

Speaking from my experiences in my own special work I wish to indicate quite shortly the possible significance of hormones in menorrhagia.

Apart from such other hormones as, for example, those of the thyroid and the suprarenal cortex—perhaps, also, the so-called circulatory hormone to which I shall refer later—there are two endocrine glands, the ovary and the pituitary, which have a particular action on the female genital apparatus.

THE OVARIAN HORMONE

Since Allen and Doisy employed their well-known test on castrated rats and mice to prove the action of this hormone on oestrus production it has become possible to prepare it in crystalline form. The best source of the hormone is the urine of pregnant women or pregnant animals, in which Zondek and Aschheim first demonstrated it, and in which it is present in large quantities. For therapeutic purposes it is not absolutely necessary to use a crystalline preparation, the manufacture of which entails a great deal of waste. I myself have had a good deal of experience with the ovarian preparation unden, which contains 100 mouse units in every tablet. The work of the biochemist in his laboratory is limited to the preparation, free from poisonous impurities, of any desired hormone and its standardization as well as possible by animal tests.

Only the practising doctor can form an opinion of the therapeutic value of such preparations. It is for him to diagnose the occurrence of cases in which the symptoms point to the presence of too little ovarian hormone, and in which the administration of a standardized preparation would be of value. According to experiences up to the present a certain number of cases can be benefited by the administration of ovarian hormone. There also occur cases in which by no means all the symptoms, and not even all cases of menorrhagia, can be thus improved.

CORPUS LUTEUM

Apart from the oestrual hormone there is at least one other hormone present in the ovary which is formed in the corpus luteum. The researches of Allen and Corner, in particular, have shown that this hormone is necessary to promote the fixation of the ovum in the mucous membrane of the uterus. Some authors believe that it also has an inhibitory effect opposite to that of the oestrual hormone, possibly also to that of the pituitary, to which we shall return later. A few authors hold that there is a co-operation between oestrous hormone and corpus luteum. Corresponding to the uncertainty surrounding the theoretical basis of the corpus luteum hormone, its therapeutic value is as yet little known. Since the corpora lutea are primarily very difficult to procure, the isolation of this hormone in sufficient quantities is for the most part almost impossible. However, according to my opinion, the hormonal function of the corpus luteum can, to a very large extent, be taken over by the anterior pituitary lobe, the function of which I now intend to discuss

ANTERIOR PITUITARY LOBE

Theory.—As is well known, Evans proved that a hormone affecting growth is secreted by the anterior lobe of the pituitary. Aschheim and Zondek, almost simultaneously with Smith, also found in this gland a hormone governing the genital function. B. Zondek, with whom I have worked in the most pleasant relationship for many years, has therefore designated the anterior pituitary lobe as the seat of the motor of the sexual function. Moreover, he also proved the presence of this hormone, which he called prolan, in the urine during pregnancy. Together with Aschheim he evolved a method of diagnosing early pregnancy by this fact. You see, during pregnancy in human beings there are two hormones present in the urine. But the diagnosis of pregnancy is only based on the early appearance of the pituitary hormone. There are important biological differences between these two hormones. For example, prolan, in contradistinction to the ovarian hormone, has no action in castrated animals. In infantile female animals it causes early maturity. According to our experiences the best experimental animal on which to prove the action of prolan is the rat. A rat unit is the smallest amount which in 66 per cent. of the animals tested under special conditions brings about complete oestrus with the formation of large follicles in the ovary. If larger doses are injected there is actually an inhibition of oestrus, and the formation of corpora lutea takes place. Zondek believes that there are two different hormones in prolan—factor A, which induces ripening of the follicles, and factor B, which stimulates lutein formation. However, it is possible that it is only a question of quantity. My experience is that any preparation which in small doses produced follicle ripening, in large doses, particularly if given for some length of time, always caused luteinization. Prolan, as it is at present recovered from the urine of pregnant women, always contains these two factors. It contains, however, no growth hormone, since this is only found in the gland itself, and is not excreted in the urine of pregnant women. Even preparations subjected to repeated purification still contain factors A and B. We succeeded in making preparations containing 20,000 to 30,000 rat units in 1 gram. They can be dissolved in water and injected subcutaneously. In contradistinction to the ovarian hormone prolan is easily dissolved in water, but insoluble in lipoid solvents. However, the watery solution of prolan is not very stable, being very sensitive to high temperatures and the least change in the H-ion concentration. Oral administration in animals has also proved effective, but here larger doses must be given. Even in the purest products it has so far been impossible, in spite of many endeavours, to isolate the two fractions A and B by chemical means. This points to the possibility of there not being two separate substances A and B in prolan, but only a quantitative difference in one uniform hormone.

Therapeutic Uses.—The following rules apply to the therapeutic use of prolan. When one wishes to stimulate the ovary to renewed activity small doses should be given, so that the so-called factor A action is obtained. If one desires to inhibit the activity of the ovaries large doses of prolan should be given, thus producing a luteinizing action. By this method, therefore, it is possible, in a roundabout manner, to obtain the specific effect of the corpus luteum hormone, which in itself is difficult to achieve. Thus every case of menorrhagia resulting from over-activity of the ovary should with advantage be treated with large doses of prolan. Already clinical experiences have proved the truth of this observation. It is therefore now possible to achieve that hormone sterilization which has for some time been sought. By combining treatment with unden and prolan together it is at least theoretically possible to regulate disturbed ovarian function.

A VASOMOTOR HORMONE

I would like to refer also, very briefly, to the substance which Frey and Kraut isolated some years ago from the urine of healthy individuals, and which proved to be

* A communication to the Section of Obstetrics and Gynaecology at the Annual Meeting of the British Medical Association, Eastbourne, July, 1931.

a product of the pancreas which lowers blood pressure They called it kallikrein—a vasomotor hormone Since this hormone dilates the peripheral blood vessels, thus lowering the blood pressure, its therapeutic use in disturbances of the climacteric may possibly be of value Whether this applies also to menorrhagia has so far not been investigated thoroughly

Conclusion

In the short time at my disposal it has been impossible to give more than a short survey of a mere part of the whole hormone question I have only touched upon those factors which I consider to be of special importance in gynaecology How great is the interest in hormones, particularly anterior pituitary, was demonstrated at the German Gynaecological Congress which I attended two months ago in Frankfort on-Main Twelve papers were read, and a further thirty speakers took part in the discussion on this subject alone Most of the papers dealt with animal experiments and were more theoretical than practical, showing that we are still at the beginning of our knowledge The new tests which the physiologist plans and works out facilitate the preparation by the biochemist of standardized hormonal preparations which can be used by the doctor Vice versa, the observations and suggestions of the doctor amplify the theoretical laboratory investigations I see in this very collaboration of several sciences the most practical way of arriving at a correct understanding of the whole hormone question. Not only is this a matter of several branches of science working together in perhaps each separate land, but collaboration between the different countries too It has therefore given me especial pleasure to appear at the Annual Meeting of the British Medical Association as a German physiologist speaking to English gynaecologists, and I am grateful for the invitation which brought this about

SOME POINTS IN CONNEXION WITH THE TREATMENT OF GLAUCOMA

BY

R H ELLIOT, M D , F R C S

LIEUTENANT-COLONEL (LATE OF I M S)

From the earliest days of the operative treatment of glaucoma, dating back over seventy years, there has always been a tendency towards the establishment of two schools of thought that which favours operative measures and that which relies on medical treatment alone Formerly there was the strongest antagonism between the two The more generally adopted view of to-day is a compromise in which both methods are made use of, each case being judged on its own merits It may be said, without fear of challenge, that no case should be submitted to operation if the use of miotics the employment of massage, and attention to the patient's general health suffice to arrest the course of the disease and to keep the case *in statu quo*

Miotics

Of the two miotic drugs pilocarpine is to be preferred to eserine in the great majority of cases for several reasons (1) It causes less conjunctival irritation (2) It does not give rise to the same measure of spasm and headache, for it acts more quietly and evenly (3) Suitably employed, it maintains the necessary contraction of the pupil quite as well as its more powerful rival

When it is a question of producing miosis as rapidly as possible in a patient with congestive glaucoma, the case is quite different, and eserine is the drug to employ Pilocarpine should be used in the weakest doses that will maintain efficient miosis, and should be given last thing at night, first thing in the morning, and about 3 o'clock in the afternoon This timing is important, for, (*a*) rises in pressure occur frequently during sleeping hours, owing to the withdrawal of the pumping action on the canal of Schlemm exerted by the ciliary and iris muscles ; and (*b*) the afternoon is, for many patients, a time of fatigue in which the vasomotor tone falls, and the pressure in the eye is consequently in danger of rising If medical treatment is to be fairly tried, miosis must be sustained Sometimes trouble is experienced owing to conjunctival irritation set up by the drug This can best be combated by the use of silver collosol, alternated with hazeline eye-drops (40 minims to the ounce of rose-water) It sometimes, however, though fortunately rarely, becomes a very serious factor in the case, making the maintenance of miosis difficult, if not impossible Operative intervention may then become a necessity

Massage

The importance and value of ocular massage in glaucoma does not seem, even now, to be sufficiently appreciated. There are certainly quite a number of cases under treatment for raised tension of the eye in which massage is either not being used at all or else not to the fullest advantage The technique is simple, and any patient can be taught to use it for himself Both hands should be used, and the index or middle fingers should be placed on the upper lid as far apart as possible and with the eyes looking downward Alternate pressure with each finger in turn will rapidly lower the tension of most eyes, but the pressure must be made toward the centre of the eye, whereas the great majority of patients employ a stroking movement which is of little value Strong pressure should not be used , light, quick, almost butterfly movements will do more good and will not hurt the patient at all In fact, he often offers the comment that he "hardly felt the massage, and does it much stronger himself" It is, however, the light, quick pressure, with the fingers far apart and with every stroke toward the centre of the eye, that is by far the most effective

the drug habit can be made too much of in such cases, a view now more widely held than formerly.

3. *Take Regular Meals and Avoid Alcoholic Excess.*—It is unwise to cut a patient off all alcohol or to limit his diet too strictly. Interference with the habits of a lifetime is often mischievous, and, to many patients, means a real deprivation. While most elderly patients are better the less alcohol they take, there are a few who are benefited by moderate indulgence in this drug.

4. *Avoid Stooping and all Sources of Strain.*—Running for trains or buses, stooping down with the head low, whether for tying a boot-lace or for weeding in the garden, lifting heavy weights, pulling on straps and cording, the straining of constipation, and any other form of strain should be avoided. This does not mean that the patient is to be an invalid. He can put his foot on a chair to tie his boot-lace; he can weed with a long-handled hoe; and he can get the younger members of his family to strap the holiday trunks. If he cannot catch the train standing in the station he can wait for the next one. He must learn his limitations and live his life as fully as possible within those limitations.

5. *Avoid all Causes of Anxiety.*—This is easier advice to give than to follow, but it is important to give it for all that. Once the importance of avoiding mental strain is realized, there is a great deal the patient can do in determinedly relegating to his subconscious mind many of the troubles of his daily life. Moreover, this is a detail in which friends and relations can do much to help. Few things have impressed me more in a long experience of this disease than the frequency with which sorrow or the crushing burden of business or family trouble proves the final factor in determining a congestive attack.

GENERAL MEDICAL TREATMENT

It is the task of the general practitioner to examine his glaucoma cases very thoroughly, with a view to improving in every possible way the general standard of health. Much that has been said and written on various bodily conditions in connexion with the etiology of glaucoma is open to question, but it is certainly important to keep the patient as healthy as possible, and so to help him ward off attacks. The subject is too wide to be dealt with further, and can be left to the practitioner's discretion and management. The mistake of using atropine instead of eserine in congested high-tension eyes is fortunately becoming much rarer with the advance of the standard of medical knowledge; but a warning may be permissible against the use of preparations of belladonna, either internally or externally, in all doubtful cases, especially when there is a family history of glaucoma.

Assuming that regular treatment has been carried out by the practitioner, it becomes the duty of the ophthalmic surgeon to test the patient from time to time with a view to ascertaining whether the condition is really stationary or otherwise. In many cases a first examination does not qualify a surgeon to give a definite opinion. It is only by making careful measurements and by comparing the records from time to time that he attains certainty in the majority of his cases. The following factors serve to guide him. The order in which they are dealt with is intentional.

1. *Tension of the Eye.*—It ought to be unnecessary to-day to emphasize the importance of tonometer readings. These should always be made under a local anaesthetic. If the drug chosen is also a mydriatic, the patient should not be lost sight of until miosis is re-established, even if it is necessary to admit him into a nursing home for the purpose. Reliance on the digital estimation of tension, though apparently not obsolete, is an anachronism. A difference in the tension of the two eyes is a sign of grave significance, especially if it does not yield quickly to medical treatment.

2. *Central Visual Acuity.*—It is often hard to get a patient to realize that this may be quite unimpaired, though the glaucoma may be steadily advancing. Indeed, in the great majority of non-congestive cases, this is the rule. A fall in central visual acuity is a distinct sign that intermittent congestive attacks have been taking place, even though such a possibility may not have been recognized either by the patient or by his medical attendant. The explanation of the oversight may be that the increases of ocular pressure occur only at night in the early history of the case.

3. *Curtailment of the visual fields* associated with a difficulty in orientation is a sign of grave significance. Constriction of the nasal side of the field and the appearance of a Roenne's step have in no way lost their importance in the past twenty years.

4. *Enlargement of the blind spot, or paracentral scotomata* are of very great importance, especially if the defects are increasing in size. They point to dangerous interference with the nerve fibres as they emerge from the optic disk. Complaints by the patient that his vision is not so good as it used to be are sometimes disregarded by the surgeon because there is full central vision in the eye. An examination with a scotometer will often provide complete justification for these complaints, which are usually founded on very real grounds.

5. *Failing light-sense* is a symptom which should never be disregarded. It is never absent in progressive glaucoma, and it is certainly one of the most distressing sequels that remain, in a large percentage of cases, long after the pressure has been relieved by successful operation. It makes things very difficult for the patient in a poor illumination, or when he goes from darkness into a bright light, or vice versa.

6.—*Cupping of the Optic Disk.*—This is perhaps the sign that most people would expect to see placed first, and it may be thought wrong to put it so late. It is the one most easy for the general practitioner to recognize, and in its typical condition, in which the whole disk is pushed backward, it is highly significant. At the same time, it is to be remembered (1) that it may be imitated by other conditions, and so there arises a common source of error in diagnosis, and (2) that a very marked glaucomatous cup may persist after all signs of the progress of the disease have been brought to a stop by medical or other means. It is not necessary to enter here into the differential diagnosis between glaucomatous and other forms of cupping. Those who are interested will find the subject fully dealt with in various textbooks. There are two points, however, to which special attention should be drawn, for they are both pregnant with meaning: (1) Considerable atrophy of the optic nerve accompanies all cases of advanced glaucoma. The pallor of the disk is of grave significance when associated with complete cupping. *The more pronounced the atrophy, the graver the prognosis of the case.* (2) An arterial pulse, on light pressure with the finger on the eyeball or after the use of cocaine or any other mydriatic, has long been recognized as a grave danger signal. It is a custom with some surgeons to use a mydriatic deliberately in order to elicit this sign. I feel mostly strongly that it is not worth the risk involved. In the past eighteen years of practice in London I have seen a number of cases in which glaucoma has been induced by the instillation of various mydriatic drugs, including cocaine, homatropine, and atropine, and in one by the injection of cocaine for the removal of a tooth. In the majority of cases when atropine was responsible, the drug had been used to produce mydriasis in order to improve vision in patients suffering from nuclear cataract. This is a most dangerous procedure. The performance of an iridectomy is vastly preferable, as it brings all the advantages of the drug with none of its risks. An arterial pulse is a sign that should always fill the surgeon with anxiety, for it shows that the eye is on the edge of a glaucoma crisis. However it may have originated, the patient should not be let out of sight until this sign has disappeared. He should be kept in bed under the influence of sedatives, eserine should be used freely, a brisk purge be given, and leeches applied to the forehead.

The surgeon will weigh all these points before deciding in favour of an operation It is very important that he should not be in a hurry, but it is essential that he should not delay a day longer than necesary, once he has satisfied himself that non operative treatment is failing to hold the disease in check. I have stressed this point for very many years Operation at the earliest moment was one of the tenets of von Graefe some seventy years ago, and de Wecker earnestly supported his master in this detail. On the other hand, no case of glaucoma is at too late a stage for trephining, always provided some sight is left. Indeed, in acute cases, even when all sight has gone, recovery to some extent may occur after relief of pressure. Needless to say that, in dealing with late material, a certain number of failures are inevitable, but there are some things that can be said without the least fear of contradiction. (1) Given an early diagnosis, one should rarely, if ever, have a failure in sclero corneal trephining. (2) The later the case the greater the risk of failure, and the greater the probability that even a technically perfect trephining, resulting in an ideal scar, may not suffice to stop the progress of blindness Few cases are more disappointing than these (3) The earlier operation is done, the better the prognosis (4) No case, however late, is hopeless if some vision still remains

THE PROGNOSIS AFTER OPERATION

As already indicated, the later the operation the worse is the prospect, though the latter is not hopeless even in very late cases in which the field is reduced to a small central area The higher the tension is before operation the greater the prospect of a material improvement after intra-ocular pressure is relieved. This is only what might have been expected, for the interference with vision under conditions of high ocular pressure is partly due to anaemia of the retina and partly to atrophy. The longer the condition has persisted the greater the atrophic element in the damage, and vice versa. Hence, in chronic cases the surgeon may be satisfied if he can keep the vision as he finds it, whilst in acute ones he can hope for a considerable restoration of function as soon as pressure is relieved.

In any operation for so serious a condition as glaucoma it is unwise to make light of the risks involved To do so may lead to very unfortunate results On the other hand, there is no need to exaggerate the risks in ordinary early and straightforward cases The surgeon's task is to put all the facts before the patient, or before his relatives, and to leave the burden of a decision on his or their shoulders In dealing with cases of advanced glaucoma it should be pointed out that it is a relentless disease, and, when progressive, leads to certain blindness In these circumstances, it is well worth while to take any means, however hazardous, that offer a possibility of escape It is always an open question whether, in desperate cases, one should put this so bluntly to the patient himself His relatives should be told the naked truth, and should be left to decide what is to be said to him, it first being pointed out to them that, both during the operation and in the succeeding convalescence, the patient's mind is supernormally active, and that, consequently, morale is a very important factor in success. The conditions are very different from those that prevail immediately before and in the days that follow many general surgical operations in which the patient is too ill or too drowsy to be able to take any interest, either in his condition or his prospects Once an operation has been decided on, everything should be said and done to keep the patient's hopes and courage as high as possible. He will then be better operation material for the surgeon. On the other hand, if he knows that his chance is a small one, and if his courage sinks, his prospect is decidedly poor. The task of encouraging him is made more easy by the excellent results that so often attend very late operations

EXPECTATION OF LIFE

This is a very important factor in a disease most of whose subjects are advanced in years The surgeon makes periodical examinations and convinces himself, in certain cases, that the disease is progressive This alone does not suffice. He must measure the rate of the downward drift, and must weigh this against the prospect of life in each individual, not forgetting that very old patients often stand the operation of sclero-corneal trephining very well indeed The family history of longevity and the vigour of the subject have to be weighed in the balance against the rate of progress of the disease Then again, there are the patient's personal predilections. One man would rather be dead than blind, and many of us will sympathize with him in this. Another dreads an operation, and will do anything possible to avoid it The general practitioner will often prove most helpful in these cases, especially when every side of the case is put plainly before him There is the further advantage that he is the patient's friend, with no suspicion of an axe to grind, and with the power of bringing a trained intelligence to bear on the difficult position which confronts his patient.

DISPLACEMENTS OF THE UTERUS AND PELVIC FLOOR*

BY

S GORDON LUKER, M D , F R C S , F C O G.

General ill-health in women (headaches, fatigue, and aches and pains) often has its origin in one of three situations—the eyes, the feet, or the pelvis If the eyes are at fault, headaches which result can be cured by suitable glasses If the feet, weakness of arches and flat foot are followed by fatigue in the feet, legs, and back This can be relieved by attention to the feet and shoes

There remains the pelvis, in which displacements of the uterus and pelvic floor are common in women who have borne children As a result, there is a constant feeling of discomfort and pain, which takes it out of the patient If there are, in addition, symptoms of menstrual dysfunction or disturbances of micturition, and these prey upon the mind, carrying fear and apprehension of evils worse than those which really exist, then the joy of life is lost and chronic ill-health results.

Displacements of the uterus and pelvic floor therefore play an important part in the health of women, and should always receive the most careful attention Until thirty years ago, the majority of those suffering from these displacements were treated with rings and pessaries, and were compelled to use a douche every day and receive medical attention every three months. Pessaries are not satisfactory, because they do not cure, require frequent attention, and, if neglected, set up discharge and sepsis. They may even be forgotten, and give rise to foul and blood-stained discharge suggesting carcinoma of the cervix These instruments have now been superseded by carefully planned plastic operations, which give perfect results Without doubt this is a great advance in gynaecology, comparable with the treatment of hernia by operation instead of by truss

The displacements may be grouped under three headings (1) retroversion or backward displacements of

* Read before the Dec. and West Lond. Med. Soc., Oct. 27, 1931

the uterus; (2) weakness of the pelvic floor alone; (3) descent of the uterus and pelvic floor. The two latter groups include all degrees of the condition generally called prolapse.

RETROVERSION

Retroversion of the uterus is either congenital or acquired. If congenital, it is unusual for it to give rise to symptoms in unmarried women. In married women it may lead to dyspareunia or sterility, or both. In single women, therefore, it is rarely the cause of symptoms, and seldom requires treatment. In childless married women it is best treated by dilatation of the cervix uteri and correction of the malposition.

The acquired variety of retroversion occurs nearly always after miscarriage or child-bearing, but may also result from inflammation or from tumours in the pelvis. It should always be treated, for if left alone it will cause symptoms, and will give rise sooner or later to prolapse. The treatment consists in correction of the position of the uterus and in maintaining this position by a Hodge pessary for three months. If this does not cure the condition the best treatment is operative—by ventral suspension of the uterus.

Retroversion as a Cause of Backache.—Retroversion rarely causes backache in single or in childless women. When the condition is discovered in the course of a routine examination too much importance should not be attached to it. In women who have borne children it may have something to do with backache and general ill-health, and is likely to be followed by prolapse. In single women, therefore, it should, as a rule, be left alone; in parous women it should always be corrected.

PROLAPSE

The anatomical supports of the uterus and the vagina are as follows: (1) the ligaments of the uterus—the round ligaments, the broad ligaments, and the utero-sacral ligaments; (2) the pelvic diaphragm, consisting of the levator ani muscle and the pelvic fascia covering it; (3) the pelvic floor muscles, of which the perineal muscles and the sphincters of the rectum and vagina are most important. These three groups all take their part in supporting the uterus and vagina; if they are congenitally weak, unduly stretched, or torn, prolapse will follow.

It can thus be seen why prolapse of the uterus and pelvic floor, though it may be congenital, generally results from child-bearing (especially when multiple), when the foetus is large, and when laceration of the pelvic floor occurs from difficult labour and instrumental delivery. Prolapse also occurs from sudden strains or overwork, but this is very unusual, even in women of the working classes. Other factors in causation are general ill-health and lack of efficient treatment during pregnancy, labour, and the puerperium.

There are five degrees of prolapse: (1) weakness or descent of the anterior vaginal wall and base of the bladder, called cystocele; (2) descent and prolapse of the posterior vaginal wall, called rectocele; (3) descent of the uterus as well as of the vagina; (4) second-stage prolapse, (5) complete prolapse.

The symptoms of prolapse are pelvic pain and discomfort, bearing-down sensations, bladder symptoms—increased frequency or incontinence are much commoner than retention—backache, and pain in the lower abdomen. The latter is not very common in patients with prolapse.

The condition of prolapse is easily recognized by inspection and examination with a speculum. Sometimes it can only be detected when the patient is standing. Its degree can be more accurately estimated when the patient is in the erect position.

PREVENTIVE TREATMENT OF PROLAPSE

It is very interesting to estimate how much prolapse can be prevented during pregnancy, labour, and the puerperium. Seeing that congenital cases are so very rare, I am of the opinion that prolapse can be prevented except in women of inferior physique who do manual labour.

During the puerperium.—Since I realized, some years ago, that retroversion of the uterus nearly always starts immediately after child-bearing, and is always the precursor of prolapse, I have invariably treated puerperal patients by great attention to anything that may prevent the onset of retroversion. These preventive methods include: (1) postural treatment—getting the patient to lie on her face for half an hour three times a day; (2) regular attention to the bladder by getting the patient to empty it regularly every six hours; (3) the promotion of involution of the uterus by suckling and by drugs such as pituitary extract and ergot; (4) examination of the patient one month after delivery. After such treatment retroversion of the uterus is nearly unknown, and very few patients have retroversion at their return visit; if found, it can be corrected at once, and a Hodge pessary given for two months.

During Pregnancy.—Preventive treatment during pregnancy aims at sufficient ante-natal supervision to keep the patient in good health and to prevent difficult labour by finding out any existing abnormality. It is particularly important to see that the foetus does not get too large for the mother and the pelvis, resulting in a prolonged and difficult labour. It is my opinion that the average woman of the present day is not able to deliver herself at her first labour of a foetus heavier than seven pounds without risk of injury. True, it is difficult to decide when the foetus arrives at that weight, but it is not difficult to judge when it is getting distinctly bigger. Such growth can be prevented, to a certain extent, by attention to the diet and by exercise during pregnancy. If the foetus is becoming too large, induction of labour should be performed.

During Labour.—Preventive treatment during labour consists in avoiding too rapid delivery by instrumental or by other means. It is important to foster the right mental attitude towards labour in the upper classes by explaining why it is necessary for them to do their "bit."

CURATIVE TREATMENT

The treatment of prolapse is by pessaries or by operation. As I stated previously, pessaries have gradually given way to operations, and should now only be used for treating prolapse in old people or in those who have other diseases or complications. The exception to this is when a woman is quite young and gets prolapse after her first confinement. If operation be carried out for the cure of such a case it is possible, though not at all certain, that the prolapse may recur after another confinement. At any rate, no guarantee can be given, so it is not advisable to recommend operation too strongly. Such a patient may prefer to temporize with a pessary and defer operation till she has finished child-bearing.

Operation is indicated in all cases except where, for other reasons, it is contraindicated. In every case a plastic operation on the pelvic floor must be done before any method of slinging the uterus from above. Ventral suspension, if performed without a plastic operation on the pelvic floor will not effect a cure in any way permanent. This was shown by the late Dr. Herman more than thirty years ago. Even if the fundus of the uterus is stitched to the posterior rectus sheath the pelvic

floor and cervix descends after a short interval, and the condition of prolapse is not improved.

For *cystocele* the operation consists in: (1) removing an adequate portion of the anterior vaginal wall; (2) pleating the base of the bladder or the platysma layer covering it; (3) approximating the two edges of the vaginal mucous membrane by mattress and continuous sutures.

For *rectocele*, posterior colpoperineorrhaphy is performed as follows: (1) remove a large triangular area of posterior vaginal mucous membrane; (2) bring levatores ani and perineal muscles together by interrupted sutures of strong chromic catgut; (3) approximate edges of vaginal mucous membrane; (4) approximate edges of skin of perineum. The cervix uteri is sometimes amputated at the time of performing anterior colporrhaphy.

The pelvic floor having now been restored to its *status quo ante*, suspension of the uterus by laparotomy may be done if necessary. This is often unnecessary in old people, in whom it is permissible very nearly to close up the vagina by the plastic operation. In younger people, who must be left nubile, the vagina must not be closed up too much, and ventral suspension is often required as a safeguard against recurrence. The best operation is suspension by attaching the round ligaments in a special manner to the midline of the anterior rectus sheath—generally called the Gilliam type of operation. I have yet to see a recurrence after this operation when performed for retroversion alone or for retroversion with prolapse, when it is preceded by a plastic operation on the pelvic floor. Its anatomical soundness is shown by the subsequent occurrence of pregnancy and labour without risk.

These operations—anterior and posterior colporrhaphy and ventral suspension—are somewhat intricate and difficult to learn, but when proficiency is acquired they give a 99 per cent. cure. Further, the worse the prolapse the less difficult the operation.

Hysterectomy is no cure for prolapse, and should never be performed unless the uterus is diseased, for it is difficult to suspend the upper vagina or cervix adequately when the uterus has been removed.

Ventral Fixation—in which the body of the uterus is stitched to the back of the abdominal wall—is not so anatomically correct as suspension by the round ligaments, and is now but rarely performed.

For severe congenital prolapse only extensive and complete operations are successful.

The Bladder and Urine in Prolapse.—It is unusual to find residual urine in prolapse, but occasionally *B. coli* is present, causing irritability of the bladder or dysuria. In such cases it is advisable to get rid of the *B. coli* before operating.

Prolapse associated with pregnancy and labour is a troublesome complication, as it is difficult to keep the uterus up during the first four months. A modified cup-and-stem pessary will help, but a good deal of rest will be essential. In labour, great care is required against sepsis, since the cervix is low down and may even come outside the vulva during delivery.

Malignant Diseases and Prolapse.—Carcinoma of the cervix or body of the uterus is but rarely associated with prolapse. When bleeding from the cervix occurs with prolapse it is generally due to traumatic ulceration.

CHILD-BEARING AFTER OPERATIONS FOR PROLAPSE

It is not advisable for a woman to have another child after colporrhaphy for prolapse has been done, as the vagina will be lacerated and prolapse recur. It is therefore quite reasonable to consider sterilization at the time of operation, which can easily be carried out by ligature of the Fallopian tubes. My own opinion is that it is definitely indicated when two living children have been born and prolapse of the second degree is present. The patient and her husband should hear the facts and make the decision.

SUMMARY

In conclusion, I will summarize the points I have tried to emphasize in this short paper.

1. Simple retroversion of the uterus in single women or in women who have not borne a child should be left alone, as it rarely causes symptoms.

2. Prolapse of the uterus and pelvic floor is preventable to some extent by care and treatment during pregnancy, labour, and the puerperium.

3. The treatment of prolapse is by operation and not by pessaries.

4. Sterilization at the time of operation is indicated in certain cases.

A CASE OF CHRONIC MENINGOCOCCIC SEPTICAEMIA WITH BACTERIAL ENDOCARDITIS

BY

W. D. H. STEVENSON, C.I.E., M.A., M.D. D.P.H., F.R.F.P.S.

LIEUTENANT-COLONEL I.M.S. (RET.)

LATE PATHOLOGIST TO THE GLASGOW MUNICIPAL HOSPITALS

Cases of chronic meningococcic septicaemia are sufficiently few in the British literature to warrant this report. G. Lovell Gulland and W. R. Logan[1] described in 1925 a case of prolonged fever in which, towards its termination, Gram-negative cocci were obtained by a blood culture. A meningitis developed, and a meningococcus was isolated from the cerebro-spinal fluid, which showed a large white cell count. At the post-mortem examination the only pathological condition of note was found in the leptomeninges. J. C. Kennedy[2] in 1926 described four cases in soldiers, in two of which meningitis supervened, and states that from 1919 to 1926 he could only find two cases in the British literature. The American literature[3 4] gives fourteen cases, with three deaths. In Dock's[5] case the post-mortem appearances were those of meningitis, which developed after seven months of fever; Gram-negative diplococci were obtained in blood culture, and, after death, from the spleen and spinal fluid. According to Marlow[3] the literature, other than American, contains approximately 110 cases.

For the clinical notes in this case I am indebted to Dr. J. C. Middleton, consulting physician to the Western District Hospital, Glasgow. During his absence on vacation the case was under the care of Dr. Andrew Allison, who sent in the blood for culture and the other material for examination.

HISTORY OF CASE

A married woman, aged 41 years, a rubber worker, was admitted to the hospital on March 8th, 1929, complaining of headache and sickness of two days' duration. The condition came on suddenly; she felt shivery; pain developed in the back; she was sick, and severe headache followed. On admission nothing abnormal was found in the heart or lungs or nervous system; the urine was seen to contain a little albumin; nothing abnormal was found in the abdomen. She became very drowsy, headache continued to be severe, and she was persistently feverish. Pus appeared in the urine, and in the absence of definite head signs the case was regarded as one of pyelitis. She was put on alkalis, and the temperature gradually came

down, but she remained drowsy and apathetic, and complained of headache. She refused to be transferred to the parish, and left hospital on May 7th. On June 20th she was readmitted.

During the time she was out of hospital she suffered from weakness and loss of energy; on June 13th she developed a troublesome cough, and applied for readmission on this account.

On readmission she was dull and listless; the temperature was 102° F. She was flushed and looked ill. There was some bronchitis present, and a systolic murmur was audible over the mitral area. The spleen was palpable. The urine contained no albumin. The pupils reacted to light, the right being larger than the left. She did not complain of headache, and there was no head retraction or rigidity of the neck. Kernig's sign was not present. Leucocyte count, 16,000 per c.mm. In a few days the cough had practically disappeared and the bronchitis had cleared up, but fever persisted. The patient complained only of lack of energy, and took no interest in her surroundings. She was perfectly clear mentally. Vomiting commenced on June 26th, and persisted. She became drowsy during the day, and this drowsiness was marked by June 28th. On July 11th she was incontinent, gradually became emaciated, and got weaker, but remained mentally clear until a few days before death, though the drowsiness increased. Fever was present throughout the illness, but there was no hyperpyrexia before death. From June 20th to 30th the temperature was irregular and remittent in type; on June 22nd and 23rd it was almost normal. From July 1st to 10th it was intermittent in type, the temperature falling below normal on every day except one, and rising to 101° up to 104° in the course of the day. From that date, while being irregularly intermittent in type, it never rose above 100.5°. During the last few days of life there was practically no pyrexia. She died on July 27th.

PATHOLOGICAL INVESTIGATIONS

The Wassermann reaction was negative. From the blood received on July 6th a Gram-negative coccus was obtained in pure culture after seventy-two hours' incubation. This coccus varied in size and intensity of staining, did not grow in subcultures between 18° and 23° C., and, while growing on agar media in first transplant, did not grow on that medium in subsequent subcultures. Growth was continued on blood-agar. It produced acid readily on maltose media—solid and fluid—and also, but later and more faintly, in glucose media. It did not acidify saccharose. Through the kindness of the public health laboratory of Glasgow, typing serums for the meningococci, obtained by them from inoculations with type cultures from the national collection, were received. On three occasions, shortly after the isolation of the organism, agglutination tests were carried out by Dryer's method. The result, I think, places the organism in the closely allied classes of Types I and III, but I was unable to classify it further.

The third test was as follows. A growth of the organism after forty-eight hours' incubation on trypagar was emulsified and diluted down by the aid of Brown's opacity tubes to 150 millions per c.cm. This was heated for one hour between 56° and 58° C. With Dryer's method, and incubation at 52° C. for twenty-four hours, the readings gave a good agglutination as follows:

Type I.—1 in 250 dilution (the titre of the serum said to be 1 in 800).*

Type II—1 in 83 dilution (the titre of the serum said to be 1 in 800).

Type III—1 in 250 dilution (the titre of the serum said to be 1 in 400).

Type IV—Only a partial agglutination, 1 in 25 dilution.

This organism was agglutinated by the patient's own serum in 1 in 125 dilution, a control serum showing no trace of agglutination. The cultural and serological tests identify the organism as the meningococcus, and as such it was reported. The fermentation of maltose and the high agglutination titre with anti-meningococcal serum distinguish it from the gonococcus, which is a commoner cause of endocarditis.

The Widal reactions against *B. typhosus*, *B. paratyphosus* A and B, and the Salmonella group, Mutton and Newport, and *B. enteritidis* (Gaertner) were negative, as also against *B. abortus* and *M. melitensis*. The patient's serum agglutinated *B. paratyphosus* C in 1 in 125 dilution, being 25 agglutination units (M.R.C.). A repeated examination of the serum taken several days later showed no change in titre. I have had on a previous occasion a high agglutination titre of the paratyphoid C emulsion in a case of a man who died from cancer, and I concluded that *B. paratyphosus* C was not the active agent in this infection. No pathogenic germs were isolated from the stool or urine. The urine contained pus, a *coli* group organism, and a Gram-positive coccus. The cerebro-spinal fluid received on July 16th showed a normal cell count—3 leucocytes per c.mm. (an average of three counts); it should be observed that the fluid had stood overnight. There was no increase of globulin. Fehling's solution was normally reduced. Cultures were made. I regret I have no note as to what developed, but that fact and my memory point to them as having been sterile.

TREATMENT

Specific serum treatment was commenced on July 13th, 25 c.cm. of anti-meningococcic serum being given daily (intramuscularly) till the 19th, when 50 c.cm. were given; this produced ecchymosis. The serum treatment was discontinued on July 22nd. The total quantity injected was 275 c.cm. No benefit accrued.

POST-MORTEM FINDINGS

The necropsy was performed thirty-three hours after death. The findings, naked-eye and microscopical, will be given in some detail, as the lesions were numerous and interesting. Over the surface of the neck and chest there was a profuse rash consisting of minute petechiae, and these were also present in the buccal mucosa.

Heart.—There was some clear fluid in the pericardium. Under the visceral layer overlying the right ventricle petechiae were present. Petechiae were also plentiful under the endocardium of the right ventricle. A soft white friable vegetation of considerable size was attached to the left cusp of the mitral valve. This consisted, on microscopical examination, of a pale thrombus, with leucocytes and masses of Gram-negative cocci attached to its free surface. The diplococcal arrangement was plainly visible in parts, and many leucocytes were packed with cocci. No other organisms were seen. At the necropsy no other peculiarities were noted in the heart, but microscopical examination of the musculature showed, especially in the wall of the right ventricle, minute abscesses in which intracellular Gram-negative diplococci could be demonstrated in the pus cells—multiple infections of each cell. Commencing necrosis of muscle fibres was present, and the condition would have been regarded as toxic had not the cocci been seen.

Lungs.—Approximately 3 oz. of clear fluid were present in both pleural sacs. There were no adhesions of pleural surfaces. The bases of both lungs showed congestion and marked oedema. Under the visceral pleura of the left lung there was some haemorrhagic mottling, with two small areas of consolidation. Microscopically the picture was one of a patchy embolic pneumonia, some alveoli being packed with pus cells, and others with red blood corpuscles, while surrounding alveoli showed an exudation of lymph. Solid clumps of Gram-negative cocci were present in the centre of some patches, but in addition clumps of Gram-positive cocci, some streptococci, and Gram-positive bacilli were also present.

Liver.—To the naked eye there was a little yellowish mottling visible. Microscopically the lobular arrangement was largely lost; liver cells were separated from each other and were of various sizes, some cells showing fatty infiltration—though this was not at all pronounced—some cells being multinucleated, and some having lost their nuclei. Many liver cells contained a yellowish granular pigment,

* The strength of the emulsions used to determine titre is not known by me.

which did not respond to tests for iron, either ferrous or ferric. Capillaries were not compressed. There was nothing of note in the portal tracts. I consider the condition to be an early toxic change, but it may possibly be a post-mortem condition.

Spleen.—This was enlarged, weighing 18 oz. No perisplenitis was present. Smears showed typical intracellular diplococci, with multiple invasion of the large endothelial cells. Sections showed some congestion of the splenic pulp, and much blood pigment throughout it. Some of the vessels were filled with aggregations of polymorphonuclear leucocytes. A few endothelial cells contained ingested red blood corpuscles.

Kidneys.—These were both pale, especially the cortex. Microscopical examination showed: (1) a somewhat thickened and adherent capsule, and (2) acute infection of several, but not all, glomeruli, accumulation of pus cells filling the tufts and cavities, and extending occasionally into surrounding tubules. In a few places the minute abscesses had started near but not in the glomeruli—probably from the afferent arterioles. Intracellular Gram-negative diplococci were seen in many pus cells; no other organisms. Other glomeruli were intensely congested. There was, however, a chronic condition present also, many glomeruli showing a multiplication of nuclei of the capillary tufts with no alterations of glomerular capsule. In others, attachment of the tuft had occurred to the outer capsule layer, and in a few fibrosis was commencing. Aggregation of lymphocytes surrounded a few glomeruli. Secretory tubules showed desquamative and degenerative changes in cells. Endarteritis was present in some small arteries. The appearance suggested there was a subacute glomerular nephritis on which an acute embolic condition had supervened.

Suprarenals.—The left showed massive necrosis with no inflammatory reaction; this may have been a post-mortem condition. The right showed minute abscesses in the cortex in which multiple Gram-negative diplococci could be observed in the pus cells; no other organisms.

Brain and Meninges.—On reflection of the dura mater a thin, diffuse, yellow, fibrinous-like deposit was seen on its under surface. The pia-arachnoid was congested, and at two sites considerable thin haemorrhagic effusion had occurred, both in the vertex—one anterior to the left parieto-occipital fissure and the other over a considerable area of the right frontal lobe. The membrane was thickened over the vertex at the inner end of the right Rolandic fissure. There was no flattening of the convolutions, no collections of pus in the sulci, the cerebrospinal fluid was clear, and the choroid plexuses were not congested. On the under surface there was some gelatinous thickening round the stalk of the pituitary body. To the naked eye no other abnormality was revealed. Microscopical examination of the cortex (including a haemorrhagic area) and of the choroid plexus gave no evidence of an acute leptomeningitis. For the most part the pia-arachnoid was oedematous, in parts showing haemorrhagic effusions. Cells were endothelial-like, and the fibrous tissue was thin.

There were, however, some noticeable features. A few veins in the pia-arachnoid were filled with a soft clot composed mainly of polymorphonuclear leucocytes with red blood corpuscles and a little fibrin. The leucocytes had separated into a dense clump. This might have been an agonal condition. A few penetrating vessels at the surface of the cortex were found to be completely blocked with the same cells. No organisms were seen. The thickened gelatinous membrane round the stalk of the hypophysis was found to consist of a cellular connective tissue, with accumulations here and there of small mononuclears and a few plasma cells. A definite minute abscess was found here, surrounded by connective tissue; it was considered to be part of the general pyaemia. Numerous diplococci were found in the pus cells; no other organisms were seen. The pia-arachnoid over the right Rolandic area and over the central lobe on the upper surface of the cerebellum was found to be definitely thickened, the newly formed tissue being a hyaline connective tissue. The subdural exudate was seen to be organized and loosely attached to the normal dura overlying. It consisted of a fine vascular connective tissue rich in large endothelial cells, some fibroblasts, and small mononuclear cells. No haemorrhages and little pigment were seen, and no polymorphonuclear leucocytes lying outside vessel walls. There was thus no evidence of an acute leptomeningitis, but there was evidence of a patchy chronic meningitis at vertex and base and over cerebellum. Nevertheless, a culture made at the necropsy from the surface of the pia-arachnoid over the vertex gave a pure growth of a Gram-negative coccus, and a smear made at the necropsy from the overlying subdural exudation showed a few polymorphonuclear leucocytes containing many typical bean-shaped diplococci and no other organisms. It may be, and I am inclined to this opinion, that the pus cells had exuded during the necessary manipulations from thin-walled vessels in which an agonal clot had occurred. It is possible, of course, to take the view that a terminal infection of the meninges had occurred so near to death that no cellular reaction had taken place.

COMMENTARY

1. The case was characterized by prolonged fever, mainly of a daily intermittent type with occasional rigors, with pronounced weakness and loss of energy, and with symptoms which may be grouped as a meningismus. The malaria-like temperature is emphasized in the literature as somewhat characteristic of subacute and chronic cerebro-spinal fever, but the clinical picture was not typical of any recognized condition, and in its terminal phase did not suggest a meningitis. A leucocytosis was present.

2. No benefit accrued from specific serum treatment; in fact, the impression of the clinician was that it exacerbated the symptoms, perhaps by liberation of endotoxins. For example, it was noted that the ecchymosis developed after the specific treatment was commenced. According to Marlow[1] certain French writers have reported adversely on the use of therapeutic serum, although he himself believes it remains the logical procedure.

3. The infection was due to the meningococcus, as shown by the cultural and serological tests. It was isolated by blood culture, and the organisms were found as a rule in smears or sections of minute abscesses in various organs. The septicaemia was associated with a recent endocarditis, producing toxic changes in the liver and kidney (in the latter probably of some standing), petechiae in the skin, buccal mucosa, pericardium, endocardium, and leptomeninges, with minute abscesses in kidneys, right suprarenal gland, lung, heart muscle, and in the thickened pia-arachnoid at the base of the brain. The pyaemic condition must have developed shortly before death, as evidenced by the size of the abscesses.

4. An acute leptomeningitis was not present, but some of the veins in the pia-arachnoid and of some of the penetrating vessels in the surface of the cortex were packed with polymorphonuclear leucocytes. It is believed that the positive culture from the pia-arachnoid over the vertex and the positive smear from the subdural exudate were due to infected cells escaped from ruptured vessels.

5. A patchy chronic meningitis was present, which may have been the residue of an early attack of acute meningitis occurring at the commencement of the illness but recovered from, and the same may be surmised of the subdural exudate.

THE AFTER-CARE OF CONGENITAL PYLORIC STENOSIS *

BY

DONALD PATERSON, M.D., F.R.C.P.

PHYSICIAN TO OUT-PATIENTS, THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET; PHYSICIAN IN CHARGE OF DISEASES OF CHILDREN, WESTMINSTER HOSPITAL

As a preface to the discussion of this problem, based on the statistics of 653 cases, I may quote two interesting and unusual cases.

1. A premature male child, which weighed 2 lb. at birth and 3 lb. at the age of 7 weeks, had vomited from the time he was born. He was at least one month premature, and died ten days after admission to hospital, with well-marked pyloric stenosis.

2. A female child, seven weeks premature, vomited from the age of 2 weeks. Periods of remission occurred up to the age of 5 months, when the symptoms became marked. Constipation was always present, but the weight slowly increased. The child was admitted to hospital at the age of 7 months, but no operation was performed in view of her poor general condition. She died at the eighth month, when marked hypertrophy of the pylorus was found at the post-mortem examination.

The first case demonstrates, I think, that hypertrophy of the pylorus is present before birth, and shows itself by the eighth month of intrauterine life. This suggests that the name "congenital pyloric stenosis" is appropriate. The second case illustrates the prolonged duration of symptoms which may occur in medically treated cases. It is a common experience that at about the sixteenth week the symptoms of pyloric stenosis pass off automatically if the case is medically treated.

MORTALITY STATISTICS

In the following table is shown the mortality in 581 cases of congenital pyloric stenosis which were admitted to the Hospital for Sick Children, Great Ormond Street,

SERIES I.—*Cases Admitted to the Hospital for Sick Children*

Year	Number of Cases	Average Age on Admission (weeks)	Place in Family: First Child	Place in Family: First Child (male)	Sex: M.	Sex: F.	Average Age of Onset of Vomiting (weeks)	Result: Cured	Result: Died	Mortality per cent.

during the period 1917 to 1930 inclusive. It may be noted that from 1923 onwards the mortality has remained almost stationary. The average age of the children on admission is also stationary, and it cannot be said that

* The substance of a communication to the Section of Diseases of Children at the Annual Meeting of the British Medical Association, Eastbourne, 1931.

cases are being operated upon earlier on the whole. The fact remains that in this large series of hospital patients one patient in four of pyloric stenosis dies, either from the operation or, more generally, from various causes during the convalescent stage.

During the last five years 36 patients were seen by me privately. Of these, one-third—namely, twelve—were treated

SERIES II.—*Private Cases*

	Number of Cases	Average Age on Admission (in weeks)	Sex: M.	Sex: F.	Result: Cured	Result: Died	Mortality per cent.
Sent to hospital	12	8·5	10	2	9	3	25
Treated privately	24	7.0	14	10	24	0	0

children of parents whose means would not allow them to have the operation performed privately, and were therefore sent to hospital; there was a resultant 25 per cent. mortality.

Of the other 24 patients whom I saw privately, all whose parents were able to afford the operation and nursing in private, all recovered. The same surgeons were responsible for the operation in both series, and the same methods were used; the difference must be attributed entirely to the environment in which the child was nursed, and to the nursing itself.

In a third series of 36 cases of pyloric stenosis admitted to a Bentinck Street Children's Nursing Home, not one

SERIES III.—*Cases Treated at a Children's Nursing Home*

Number of Cases	Average Age on Admission (in weeks)	Sex: M.	Sex: F.	Result: Cured	Result: Died	Mortality per cent.
36	6.5	29	7	36	0	0

of these 36 infants has died. A variety of surgeons, some less expert than others, performed the operation, but with concentrated nursing attention these most excellent results have been obtained. Dr. G. F. Still informs me that he has not had a single death in private practice from pyloric stenosis where Rammstedt's operation has been employed.

AGE OF THE INFANT AT OPERATION

It has been argued that the crucial point in lowering the mortality was the duration of the condition before diagnosis and operation. I do not combat the fact for a moment that the earlier the operation is done the better is the prognosis; but in the series of private cases as contrasted with the hospital cases, the average age at which the operation took place was identical.

THE OPERATION

Again, it has been contended that the type of surgical treatment seriously influenced the mortality. Dr. S. published a series of 47 consecutive private cases with only one death, the operation being that of Loretta in all cases. This has been given up, and with the new procedure of Rammstedt the operative risks have been considerably lowered. Undoubtedly the introduction of anaesthesia was a great step forward. Lately, local anaesthesia has been given an extensive trial in a series of 50 hospital cases, and the mortality has been less than a further 5 per cent. The advantages of a local anaesthetic are, briefly, that the baby can be fed directly it returns to the ward, and is not flabby and unwilling to take food; shock is reduced to a minimum, and the cough reflex is still present, thus avoiding aspiration of the lungs from regurgitation of the gastric contents during operation. The anaesthetic used is 0.5 per cent.

ithout adrenaline, the baby is bandaged to Denis rowne's cross, and a dummy dipped in glycerin is sed to soothe it There is greater responsibility for the urgeon, since, with straining, sewing may be difficult

Alkalosis in Pyloric Stenosis

The work of Maizels, McArthur, and Payne[2] is of the reatest importance, and has passed almost unnoticed by nany They point out that, with repeated vomiting and oss of hydrochloric acid over a prolonged period, there s a marked tendency for the chloride content of the plasma to be lowered The almost universal habit of washing out the stomach with a solution of sodium icarbonate, usually directly before the operation, tends o induce a state of alkalosis The very familiar picture after operation of slow, gasping respirations, pallor, and collapse, was the direct result of this procedure With this knowledge, the avoidance of bicarbonate lavage, and the extensive use of saline solution and glucose subcutaneously, such a clinical picture has disappeared

Post operative Feeding

Improvements in post-operative feeding in the past few years have probably assisted to lower the mortality, to prevent diarrhoea, and to hasten convalescence of pyloric cases Breast milk should be used unquestionably in preference to any other food when it is available, but in other cases some artificial food must be employed My usual feeding regime is as follows

Four hours after the operation there is given, at hourly intervals 1 drachm of one of the following breast milk, or half-cream Cow and Gate dried milk mixture (or Dryco or Klim skimmed) made up one measure to each ounce of water, or unsweetened condensed evaporated milk mixture, or lactic acid milk and water mixture Twelve hours after the operation there is given, at hourly intervals, 1½ drachms of the food selected Eighteen hours after operation, at intervals of one and a half hours, 2 drachms of the food chosen are administered gradually increasing until twenty four hours after the operation 1/2 ounce of the food is being given at two hourly intervals If the infant is breast fed it should be suckled at three hourly intervals from this time onwards If it is not breast fed 2 ounces of the food chosen are given thirty six hours after the operation, at three hourly intervals while at forty eight hours after the operation almost the full amount for the infant's weight can be administered

The unsweetened condensed evaporated milk mixture is made by adding one part of this to four parts of water, one heaped teaspoonful of Demerara sugar being introduced into each 4 ounces of the mixture For the preparation of the lactic acid milk and water mixture thirty five drops of lactic acid (*B P*) are added drop by drop to one pint of skimmed cow's milk which has been boiled and allowed to cool during the addition of the lactic acid the milk is well stirred and sugar is added The mixture should be given diluted at first with an equal quantity of water

As regards the feeding in medically treated cases, breast milk should be continued if plenty is available, failing this, the milk mixture thickened with one of the starchy patent foods (for example Savory and Moore's or Benger's food added to a mixture of cow's milk and water in equal parts, the whole having the consistency of cream), will be found the most successful Small, concentrated feeds are desirable, since they are of high caloric value, even if only a small quantity is retained the infant tends to thrive Lactic acid can be added to the cow's milk if thought advisable

Conclusion

The obvious conclusion to be drawn from this very large and unique series of cases is the value of nursing and good environment to the child after operation What are the advantages to the child who is treated privately?

First, it cannot be too strongly pointed out that the risk an infant runs in an ordinary hospital ward of contracting infections from other children is very great Respiratory and gastro-intestinal infections in other inmates of the ward are readily contracted by the debilitated congenital pyloric stenosis case With private treatment the infant is in a room by itself, and the possibility of such an infection is carefully guarded against

Secondly, and of even greater importance, is the nursing care which a very ill infant requires No hospital ward in this country can provide more than one nurse to four or six infants and children during the twenty four hours This means that the infant is sharing the attentions of a nurse with several others, which must necessitate the work being done imperfectly In addition, those nurses are young, and in process of learning their profession During the night period, in a ward of from 12 to 26 beds, there are, as a rule, two nurses, and for twelve hours the infant can only have a fraction of their attention

In private practice, for twenty four or forty-eight hours at least, the infant receives the entire attention of a skilled day nurse, and also a night nurse, such nurses, with a repetition of cases, becoming most experienced, and, in fact, being able to cope almost unaided with any situation which may arise It would appear to me that the lowering of the mortality must be attained by the separation of pyloric stenosis cases from all others, the nursing of these cases by themselves, and the realization by the public and the profession that the intensive nursing required in such a case for a short period must be provided

THE USE OF AN ANTISEPTIC (QUINANIL) WITH PREPARATIONS OF GONADOTROPIC SUBSTANCES

BY

J M ROBSON, M D, B Sc

(From the Macaulay Laboratory Institute of Animal Genetics, University of Edinburgh)

In the course of work done on the pregnancy changes in the uterus, a number of experiments were performed in which the effects of various pituitary preparations were investigated in rabbits, when bovine pituitaries, in a finely divided form, were used for injection it was found that the site of injection almost invariably became septic, whatever the precautions taken As it was impossible to sterilize the pituitaries by the ordinary methods available without destroying the activity of the gonadotropic factors, it became necessary to use some type of antiseptic, and an attempt was made to obtain a suitable substance It was realized that the substance used should have a high antiseptic power, its toxicity should be low, and, most important qualification, it should not destroy, or interfere with the action of the gonadotropic factors of the pituitary Putnam, Teel, and Benedict (1925) have investigated the action of a number of antiseptics on gonadotropic factors obtained from anterior pituitary lobes (alkaline extracts) They found that alcohol, phenol, acriflavine, mercurochrome, and benzyl resorcinol either destroyed or precipitated the active principles, and had ultimately to resort to filtration through a Seitz filter in order to obtain a sterile preparation

It was of course impossible to use this method when the actual pituitary was being injected, and it was decided to try other antiseptics Quinanil appeared to be suitable in view of its properties This antiseptic is a derivative of a substance 2 4-dimethyl-amino-ar-ll 6-methyl-quinoline metho-chloride, originally described

by Browning, Cohen, Ellingworth, and Gulbransen (1926). It has been bacteriologically and clinically investigated by Gordon and Armitage (1929); its antiseptic power is two to three times as great as that of acriflavine, and is little affected by the presence of serum; its toxicity is low; the mean dose tolerated by a rabbit (4½ lb.) is of the order of 9 c.cm. of a 0.5 per cent. solution when the drug is injected intravenously, and comparatively large doses (up to 50 c.cm. of a 0.1 per cent. solution) have been injected in human subjects without any apparent ill effects.

The antiseptic was mixed with the finely divided pituitary tissue (1 to 2 c.cm. of a 0.5 per cent. solution in Ringer-Locke solution to 1 gram anterior pituitary lobe) and injected into rabbits intramuscularly. It has been shown (Robson, 1931) that the injection of anterior pituitary lobe into female rabbits is followed by the formation of corpora lutea in the ovaries and the concomitant changes in the uterus—that is, proliferation of the endometrium and inhibition of the *in vitro* reaction of the muscle to pituitrin. These results were still obtained in all experiments when quinanil was added to the injected material, and there seemed thus to be no interference with the gonadotropic action of the pituitary active factors. The antiseptic was entirely successful in preventing sepsis at the site of injection; in previous experiments (without antiseptic) many animals had died within a few days, and no animal had remained alive for more than fourteen days after the first injection. With quinanil, on the other hand, no abscesses developed; the animals remained alive and in good health (no loss of weight or diarrhoea) as long as the experiments were continued (more than twenty days in several cases).

In view of these results it was decided to investigate more extensively the suitability of the antiseptic for administration with preparations of gonadotropic factors. Quinanil was added to a water-soluble protein-free alkaline extract of the pituitary (for which I am greatly indebted to Dr. B. P. Wiesner), and injected intravenously into rabbits. The usual corpus luteum formation in the ovary and changes in the uterus were obtained, showing that the potency of the preparation had not been materially affected. The effect on active factors obtained from the urine of pregnant women was then investigated; preparations made by alcohol or phosphotungstic acid precipitation (Wiesner and Marshall, 1931) were mixed with quinanil and injected intravenously into rabbits. Follicular maturation, ovulation, corpus luteum formation, and the usual effects on the uterus were obtained, showing that quinanil again did not interfere with the action of the gonadotropic principles.

Lastly, a number of experiments were performed on mice by Mr. P. G. Marshall (to whom I am indebted for permission to quote the results). A preparation made from the urine of pregnant women by the alcohol precipitation method was dissolved in 0.85 per cent. saline and sufficient quinanil added to make a 1 in 1,000 solution. Various quantities of the solution were then injected into mice; the effects obtained (blood spots, corpora lutea, distension of the uterus) were similar to those given by control experiments in which no quinanil had been added to a fraction of the same pregnancy urine preparation. From these experiments it can also be concluded that quinanil does not destroy or materially impair the activity of gonadotropic factors.

The effect of more prolonged action of quinanil on gonadotropic factors has not been investigated. In all experiments, the active material was used within a few days of its preparation (unless it was kept in the form of a dry powder), and the solutions made up with quinanil were also used within a similar period.

In addition to the use in experiments, quinanil has also, in a number of cases, been added to samples of gonadotropic factors (prepared from pregnancy urine) which are sent out from this laboratory for clinical use. Sufficient data have not yet been obtained, however, to pass any opinion on this use of the antiseptic.

SUMMARY

Experiments have been made to determine whether the antiseptic quinanil destroys or interferes with the action of gonadotropic substances. Used in conjunction with finely divided anterior pituitary lobe, and with extracts made from anterior pituitary lobe or pregnancy urine, injected subcutaneously and intravenously into rabbits and subcutaneously into mice, no appreciable decrease in the gonadotropic effects on the ovaries (and the resultant changes in the uterus) was detected. It is suggested that the antiseptic may be suitable for use in the clinical administration of these hormones.

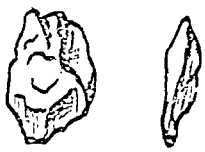
Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

FOREIGN BODY IN A CHILD'S BRONCHUS WITH ATYPICAL SIGNS AND SYMPTOMS

The occurrence of a ball of paper as a foreign body in the air passages of a child is in itself unusual. In the following case the history and physical signs were atypical, and the presence of the foreign body was not suspected until it was expectorated.

A boy aged 6, who had previously been quite well except for an attack of bronchitis in 1925 and measles in 1926, was admitted to Highgate Hospital on May 6th, 1931, with the history that two days earlier he had seemed feverish, and complained of headache and pain in the back, and had developed a spasmodic cough which sometimes induced vomiting.



On admission his temperature was 99° F., pulse rate 96, and respiration 34. His tongue was furred, the tonsils enlarged and injected without exudate, and his breath smelt of acetone. Movement of the chest, percussion note, air entry, and breath sounds were normal, but there were a few crepitations to be heard along the vertebral border of the right scapula. Physical examination revealed no other abnormality.

On May 7th he was lethargic, with flushed face, lost his appetite, and a troublesome cough. The percussion note was now impaired, and the air entry diminished at the right apex over the area of the right upper lobe. There were no adventitious sounds. By the morning of May 9th the percussion note was markedly impaired, and the breath sounds were loudly bronchial over the whole of the right upper lobe. During that night the patient had a paroxysm of coughing and expectorated a flat plaque three-quarters of an inch in diameter and half an inch thick, which weighed 12 grains. It had a hard, brownish-yellow external crust over a soft interior, and was soaked in offensive sputum. On May 11th the child was delirious, with dry, thickly furred tongue; physical signs in the chest were unaltered. During the night, however, the temperature fell by crisis.

On May 11th the patient began to take an interest in his surroundings, and his appetite returned; the tongue became moist and was less furred. The consolidation of the right upper lobe was unchanged, but scattered fine rhonchi were heard in all other areas. On May 12th the percussion note was slightly less impaired, and a few redux crepitations were present over the area of the right upper lobe. Fewer rhonchi were heard in the other pulmonary areas. From this time he made rapid progress until May 25th, when physical examination of his chest revealed no abnormality, and on discharge on June 16th he was perfectly well.

After convalescence an *x*-ray photograph of the chest was taken with the foreign body so placed that, with the whole thickness of the chest between it and the plate, its shadow fell as nearly as possible in the region of the right bronchus. The foreign body cast a definite and well-recognizable shadow.

On September 9th the patient was brought up to the hospital by request for examination. His father stated he had been perfectly well since discharge, and no cough had been noticed. On physical examination his chest was found to be normal, and this was confirmed by screening and radiography,

Sketch of foreign body (actual size).

which showed the movements of the chest and diaphragm to be normal and the lung fields clear.

Dr. F. H. Shaw reported as follows on the foreign body:

A flattened body, three-quarters of an inch in diameter, having a gritty, friable shell containing soft layers of paper. Microscopically, fibres of paper were seen, having the same appearance as other samples of paper examined for comparison. Evidently, a small ball of paper covered with organic matter infiltrated with phosphates.

The points of interest in this case are:

1. The nature of the foreign body and the fact that, had its presence been suspected, it could have been revealed by radiography.

2. The phosphatic incrustation, which had formed very rapidly if the foreign body had been present in the air passages since just before the onset of the acute illness. The alternative, that the ball of paper had been lying in the bronchus for some time without producing symptoms, does not seem possible, on account of the size of the ball.

3. The absence of a characteristic history. Neither the boy nor his parents could remember a choking fit or any symptoms suggestive of the inhalation of a foreign body.

4. The course of the acute illness and the character of the physical signs, which were both those of an ordinary lobar pneumonia.

My thanks are due to Dr. F. H. Shaw for examining and reporting upon the nature of the foreign body, and to Dr. C. Thackeray, the medical superintendent, for permission to publish this case.

Late Assistant Medical Officer, Highgate Hospital.

SKIN INFECTION IN CANINE VISCERAL LEISHMANIASIS

Blanc and Caminopetros observed ulceration of the skin in canine visceral leishmaniasis in Greece. The ulcers, like those produced by *Leishmania tropica*, contained Leishman-Donovan bodies. Parrot, Donatien, and Lestocquard (1930) found that sandflies (*Phlebotomus perniciosus*) which fed on dogs with cutaneous ulcers became infected with leishmania. Working in Malta, we found that wandering cells infected with Leishman-Donovan bodies are distributed almost uniformly throughout the intact dermis in all parts of the body. Infection of the dermis is present even in animals with a very slight visceral infection. Sandflies (*P. perniciosus*) were fed on the unbroken skin of a dog with a slight visceral infection, and 32 per cent. of the insects became infected. Feeding experiments with *P. perniciosus* on the unbroken skin of two other naturally infected dogs gave infection rates of 62 and 65 per cent. respectively. None of the animals had cutaneous ulcers during the time the experiments were carried out. Spleen smears of all the three dogs showed Leishman-Donovan bodies, but in much smaller numbers than spleen smears of average human cases of infantile kala-azar, which give a relatively low infection rate with *P. perniciosus*. Examination of blood smears of the experimental animals showed no Leishman-Donovan bodies.

The above findings show that *P. perniciosus* infects itself with leishmania by ingesting skin juices of infected dogs during the act of biting. The behaviour of the canine strains in *P. perniciosus* was very similar to that previously recorded for human strains of *L. infantum*—that is, the flagellates tend to an anterior position.

GENERALIZED GAS GANGRENE DEVELOPING DURING PARTURITION

It has been shown by Wrigley[1] that uterine puerperal infections by Welch's bacillus are more common than is generally believed. Wrigley has demonstrated that such infections are usually met with in cases in which a dead foetus has remained for some time in the uterus, and that severe and fatal cases usually follow intrauterine manipulations. Severe cases of puerperal gas gangrene are nevertheless uncommon. The case that is now recorded is exceptional, because a generalized infection, which resulted in gas formation in the subcutaneous tissues before death, arose during the first stage of labour, and caused a fatal termination before the third stage was completed.

HISTORY OF THE CASE

A married woman, aged 25, was admitted to the London County Council Special V.D. Hospital for pregnant women, Thavies Inn, on May 24th, 1930, during the sixth month of her pregnancy.

The patient was a syphilitic, and had had four previous confinements, dating from 1920. The first baby died thirty-six hours after birth. During the second pregnancy the patient was treated at Thavies Inn with anti-syphilitic measures, and was delivered of a child which, treated anti-syphilitically, ultimately survived and appeared quite well. Anti-syphilitic treatment was carried out during the third pregnancy at Thavies Inn. The child was born alive and survived under anti-syphilitic treatment. During the fourth pregnancy no anti-syphilitic treatment was given on account of the patient's living in the country. The labour was difficult and instrumental, and the child was born stillborn.

During her fifth pregnancy the patient was again admitted to Thavies Inn clinic, in May, 1930, when it was found that the Wassermann blood reaction was strongly positive. Anti-syphilitic treatment was immediately commenced. Parturition was expected during the first week in August. At 9.15 a.m. on August 6th, 1930, the patient felt ill; she had a temperature of 101° F., and pulse 104. There were no labour pains, but there was an offensive vaginal discharge. On examination the os was found to be closed. At 10 a.m. slight labour pains commenced; temperature 103°, pulse 104. At 1 p.m. the os was found to admit one finger; at 2 p.m. it was noted that the patient was passing gas from the vagina, and at this time she began to vomit. At 3 p.m. the os was found fully dilated. The temperature and pulse were now normal. At 5.15 p.m. labour pains were strong, but there was no advancement of the head; it was noted at this stage that the patient's face and neck had become puffy. At 7.15 p.m. she was delivered of a macerated male foetus. The head was born naturally as a left occipito-anterior, but there was difficulty in extracting the body of the child owing to its tissues being puffy and decomposed. The placenta was retained, and an unsuccessful attempt to remove it was made manually.

At 8.30 p.m. the patient was seen by Dr. Wilfrid Shaw, who confirmed the diagnosis of gas gangrene. At this stage palpation of the uterus from the abdomen elicited the typical crackling of subcutaneous emphysema. It was also found that crackling could be obtained in the subcutaneous tissues of the abdominal wall, and the swelling of the face and neck was demonstrated to be due to gas emphysema. When the uterus

[1] Wrigley, A. J. *Proc. R. Soc. Med.*, June, 1930.

was pressed down, large bubbles of gas were passed per vaginam. The patient's extremities were cold, and the pulse was hardly perceptible; she was quite sensible, and answered questions intelligently. The condition was clearly a septicaemia due to infection with gas-gangrene organisms.

An examination of the foetus showed gas emphysema, which had been responsible for the difficulty in extraction. The foetus was in an advanced stage of maceration, and had probably been dead for some time.

The prognosis seemed hopeless: 30 c.cm. anti-gas gangrene serum was injected intramuscularly, and a copious intrauterine douche of peroxide solution was given. The patient's general condition rapidly became worse, the emphysema extending rapidly over more of the subcutaneous tissues of the trunk and scalp. The patient died at 1.30 a.m., six hours after the birth of the child.

A post-mortem examination of the mother could not be obtained. An exact diagnosis of the condition was not possible without bacteriological evidence, but the condition of emphysema and the passage of large quantities of gas per vaginam, together with the condition of the foetus, demonstrated almost conclusively that general infection with gas-gangrene organisms was the cause of death.

The case is recorded because of the rarity of this complication of pregnancy; the most remarkable feature was the presence of a widely distributed emphysema in a living patient, for such a widespread emphysema is usually a post-mortem phenomenon. This case illustrates the accuracy of Wrigley's contention that gas-gangrene infections of the puerperal uterus arise in connexion with intrauterine death of the foetus. In the case now recorded the intrauterine death of the foetus was almost certainly to be attributed to syphilis in the mother, but the mode of infection of the uterus is obscure. A point of importance is the fact that the temperature rose before any vaginal examination was made. The evidence available, therefore, disfavours the conception that the infection was exogenous.

Emphasis should also be placed upon the rapidity with which the patient died, death occurring within seventeen hours of the onset of symptoms.

CLINICAL AND SCIENTIFIC PROCEEDINGS

WEST DORSET DIVISION

Modern Treatment of Deafness

At a meeting of the West Dorset Division, held at Sherborne on November 26th, Dr. GEORGE C. CATHCART (London) read a paper entitled "The modern treatment of deafness".

It had to be remembered, Dr. Cathcart said, that otology was one of the youngest branches of science, and only of late years had any treatment of the deaf begun; the knowledge gained by specialism had still to filter through until it became part of the ordinary curriculum of the medical student. Yet prevention was beginning to play its part, and already there was a great change in the type of case seen in adult life. A few years previously the mastoid operations that had to be performed for chronic ear discharge in order to save life were infinitely more numerous than at the present day. This was undoubtedly due to the greater care taken of the ears during the course of measles and scarlet fever, and also to the more frequent removal of adenoids and the more thorough extraction of septic tonsils by enucleation instead of by the guillotine. Chronic catarrhal otitis media was undoubtedly the commonest form of deafness. It was, however, the only form which was not hereditary, and might be prevented by the removal of adenoids and enlarged tonsils in childhood, and, more especially, by timely paracentesis and removal of the fluid in the ear before it had time to organize. Catarrhal otitis media ought to be curable, if treated in the early stages. A few years previously the presence of an intact drum and ossicles was considered an absolute essential to hearing, and a large number of the laity, even the well educated, still raised strong objections when the question of paracentesis was mooted. It was now known, however, that the sounds reached the inner ear by means of the round window, and so long as that was healthy the drum was of minor importance. For nerve deafness hitherto there had been no treatment. The sufferers were told to try various drugs, to stop smoking, not to worry, to lead a sober life in the future if they had not done so in the past, and, above all, not to waste any more money on doctors, since no one could do them any good. Nor was the prospect any more pleasing as regards the treatment of chronic otitis media. Sir William Milligan had given it as his opinion that there had been no substantial progress in the treatment of adhesive catarrh of the middle ear during the past twenty years.

Dr. Cathcart said that for many years he had been of the same opinion, and had tired of having to tell so many patients, after the classical remedies had failed, that nothing more could be done for them. A few years ago, however, he heard, through an old patient who had been successfully treated by it, of a new method of treating chronic progressive deafness—namely, the electrophoniode method originated by Zünd-Berguet of Paris. The electrophoniode was an instrument which reproduced the sound vibrations of the whole gamut of the human voice, and thus gave a physiological stimulus to the ear. The sounds produced were of varying quality, and were variable at will; they were transmitted to the ear by telephonic receivers, which could be adjusted to the sensitiveness of each ear. Finally, a secondary current, producing a gentle, short-wave vibratory massage of the ear, was superimposed on the primary one which made the sounds; it was to this double action that the successful results were attributed. This method of treatment laboured under the disadvantage that it was not possible to tell from any tests made beforehand whether it would be successful or not. There was a factor in deafness as yet unrecognized, the presence of which—or it might be the absence of which—determined the result. The usual course of treatment consisted of fifty sittings, but on account of this unknown factor it was necessary to give a preliminary course of twelve sittings to find out whether it was worth while to continue or not. Up to the present Dr. Cathcart had treated 665 cases of chronic deafness by the Zünd-Berguet electrophoniode method comprising 187 cases of nerve deafness, 261 cases of chronic otitis media, and 217 cases of otosclerosis. Of the 187 cases of nerve deafness 138 (73.8 per cent.) improved, while 49 did not benefit to any appreciable extent. Of the 261 cases of chronic otitis media 174 (66.6 per cent.) improved, while 87 did not do so. Of the 217 cases of otosclerosis 117 (53.9 per cent.) improved, while 100 were unaffected. This amounted to a total of 665 cases of chronic progressive deafness, of which 429 cases (64.5 per cent.) improved after treatment by the Zünd-Berguet electrophoniode method, while 236 cases failed. Records showed that this treatment not only alleviated tinnitus, or noises in the head, but often caused it to disappear completely; 36 out of the first series of 100 patients suffered from tinnitus, which ceased after treatment in 26 (72 per cent.), while in the remainder 10 cases the noises were much lessened, although they did not cease. In the total of 665 cases there were 230 cases of tinnitus, of which 158 (68.7 per cent.) improved after treatment.

Reports of Societies

X RAYS IN THORACIC DISEASE

At a meeting of the Medical Society of London, held on December 14th, with the president, Mr. HERBERT TILLEY, in the chair, a discussion took place on the value of *x* rays in the diagnosis of thoracic disease.

Dr. P. J. KERLEY, in opening the discussion, chose the subject of congenital diseases of the lungs as illustrating recent advances in chest radiology. These congenital lesions found no place in the ordinary textbooks because they could not be diagnosed by ordinary methods. One of them, revealed by *x* rays, was an abnormal azygos vein, found to be present about once in every two hundred individuals. In many cases this vein actually split the right upper lobe into two distinct parts, each with a separate vascular and bronchial supply. The *x*-ray appearances were characteristic, the pleura, as it ran through the lung fissure made by the vein being seen as a curved white line. If the vein made a deep indentation, the piece of upper lobe thus cut off was always very congested, and this gave rise to physical signs indicating pulmonary tuberculosis. If pneumonia occurred in such a lobe, delayed resolution or even abscess formation might result. Carcinoma and bronchiectasis might occur in this azygos-vein-lobe and an interlobar empyema might develop in the abnormal fissure. Turning next to more common and more dangerous anomalies of the lungs, the speaker mentioned certain deformities of lung architecture. He said that there was a persistent tendency in man towards the formation of a fourth lobe in the right lung and a third lobe in the left lung. In about 15 per cent. of individuals such an accessory lobe could be found, and it was bilateral in about 1 per cent. The fissure dividing the accessory lobe from the rest of the lung was quite clearly visible in a radiograph. Dr. Kerley dealt with some points on the comparative anatomy of this accessory lobe, and pointed out that when it was supplied by a bronchus of the third degree with no cartilage in the walls, it was almost a certainty that collapse and bronchiectasis would occur. He described the *x*-ray appearances of a collapsing accessory lobe, showing how they were usually described as collapsed lower lobes due to bronchiectasis. Actually, bronchiectasis followed the collapse, partly owing to deflation of the lobe, but also as a result of congenital malformation of the alveolar structure. In two cases pulmonary tuberculosis had occurred in an accessory lobe and in three cases carcinoma had been observed. The association of carcinoma with foetal atelectasis had been commented on by other workers. In conclusion, the speaker dealt with the question of treatment in these congenital lesions. Early diagnosis by radiography was essential. Good results had been reported by inducing artificial collapse. The only rational method of treatment, however, in Dr. Kerley's opinion was removal of the abnormal lobe.

Dr. F. G. CHANDLER said that the application of *x* rays to the investigation of intrathoracic disease had proved to be one of the greatest diagnostic advances ever made. *X* rays, however, should never supplant or render obsolete such diagnostic aids as clinical observation, physical signs, the exploring needle, bacteriological investigation, and even bronchoscopy or exploratory thoracotomy. The speaker then enumerated the many lung lesions where *x* rays gave very valuable help in diagnosis, and continued with a discussion of some of the limitations and difficulties of radiography of the chest. In the first place, he emphasized that the skiagram was only a shadowgraph, possessing no morbid anatomy, with pattern but not structure. Without a full clinical knowledge of the case, interpretation of such shadows might be impossible. This also applied to the estimation of the activity of a lesion by *x* rays alone. An increase in the areas of diseased lung seen in successive skiagrams was the only certain evidence to be obtained radiologically. As an example of the error in making a diagnosis solely from radiological appearances, Dr. Chandler showed pictures from a case where a large shadow, apparently encysted fluid, existed for ten years in the chest of a perfectly healthy woman. Technical faults such as bad skiagrams led to mistakes from time to time, while certain traditional errors, as in the differentiation between peribronchial tuberculosis and normal or harmless root shadows, were still perpetrated. There was often considerable difficulty in the early diagnosis of malignant disease of the lung, a subject of vital importance. The growth might be too small to give a shadow or there might be various secondary changes obscuring the true condition. The speaker next mentioned the importance of a lateral view, especially where an opacity was obscured by the heart shadow. There must always be limitations in radiography because of the size of the lesion; hence the futility of attempting to exclude early pulmonary tuberculosis by an *x*-ray examination. Other limitations resulted from the lesion being transparent: a foreign body, for example, might be quite impossible to see in this way. Bronchi were, as a rule, transparent, hence the value of lipiodol in the diagnosis of bronchiectasis. Dr. Chandler mentioned that he was now using the oral method exclusively for the injection of lipiodol. In conclusion, he said that, while radiology of the lung must always be supported by symptoms, history, physical signs, and special methods, he would, if limited to one method of diagnosis only, choose the former.

Dr. STANLEY MELVILLE, discussing some aspects of neoplastic disease of the lungs, said that only in a strictly pathological sense could any distinction be drawn between benign and malignant neoplasms, since a simple fibroma grew in size, and in the course of time might kill by pressure. In the early diagnosis of such new growths by means of radiography it was easy to distinguish between simple and malignant tumours, as benign neoplasms were extrapulmonary, rounded, and well defined. The diagnosis was aided in many instances by inducing collapse of the lung. He quoted certain statistics concerning the incidence of malignant disease of the lung, and asked for definite views as to whether the increase was a true one or only apparent.

Dr. R. A. YOUNG pointed out how two almost accidental discoveries had revolutionized medical diagnosis of lung disease—namely, the discovery of *x* rays by Roentgen and of lipiodol by Sicard. He thought that *x* rays were useful from three points of view. First, they opened up a field of interesting anatomical and pathological research; secondly, they were of increasing value in diagnosis; and, thirdly, they were of increasing value in the study of the progress of disease in the lungs, and were therefore helpful in prognosis. He thought that surgery of the lungs had been greatly aided by *x* rays, and owed a great deal to the modern advances in radiology. Dr. Young went on to say that dermoids of the lung were commoner than he used to think, and it was important that they should be recognized early, and dealt with. Fibromata were not harmless tumours, and might cause serious pressure symptoms or lead to abscess formation. Care should always be taken to correlate *x*-ray findings with clinical conditions.

Dr. L. S. T. BURRELL agreed that he would choose radiography if limited to one method of diagnosis, but it was very difficult for the physician to decide what should be done with a patient by an *x*-ray examination only. He had seen one patient with a shadow almost identical with that in another case of fatal carcinoma, yet

the patient had lived for four years after operation had been refused. If there was this uncertainty in the early stages of carcinoma, it was difficult to urge serious operations. Dr. A. J. SCOTT PINCHIN held that it was important to place x rays in their right position. Early diagnosis of carcinoma by their aid would, in most cases, still be too late to allow of satisfactory treatment, and it was important to get even earlier evidence by the bronchoscope. He believed malignant disease was really on the increase, though he mentioned that, whereas before the war mediastinal sarcoma was the commonest thoracic tumour, of recent years carcinoma of the bronchus had replaced it in frequency. In the last year, however, mediastinal growths had turned up again in greater numbers. Dr. B. E. SCHLESINGER mentioned the so-called epituberculosis, common at the left apex, where a non-specific reaction occurred around a tuberculous focus, and also referred to the fact that when phthisis arose in children it was commoner at the base than at the apex. Dr. W. BURTON WOOD said that x rays had shown there was a benign form of acute tuberculosis of lung. This was probably akin, pathologically, to epituberculosis. Large, soft shadows appeared, which all cleared up eventually. Mr. C. DICKSON WRIGHT expressed his gratitude that an explanation of various difficult shadows seen in x rays of the lungs had now been offered. He thought that injection of lipiodol was often eschewed because of discomfort to the patient, but with the nasal route recently described the process was really very simple. He asked for the latest views as to the nature of pleural rings seen in skiagrams. Dr. M. DAVIDSON pleaded for greater co-ordination in the x-ray diagnosis of diseases of the chest. The idea of team work was more honoured in the breach than in the observance. He also mentioned the importance in diagnosis of the clinical history, especially of early malignant tumours of the lung. In connexion with the term "infiltration of the lung" he pointed out that radiologically there was no difference between infiltration due to tuberculosis and that due to other causes—for example, actinomycosis.

The PRESIDENT spoke of certain patients in whom radiology had greatly helped to clear up a diagnosis, but a bad skiagram, he said, might well be worse than no skiagram at all. In replying to the discussion, Dr. KERLEY said that there was no such thing as a pleural ring, and the modern view held that these shadows always represented cavities.

RIFT VALLEY FEVER OR ENZOOTIC HEPATITIS

At a meeting of the Royal Society of Tropical Medicine and Hygiene, held at the School of Hygiene and Tropical Medicine on December 10th, with the president, Dr. G. CARMICHAEL LOW, in the chair, Dr. G. M. FINDLAY read a paper on Rift Valley fever, or enzootic hepatitis.

In his introductory remarks Dr. Findlay pointed out that enzootic hepatitis was first described by Daubney, Hudson, and Garnham (1931) in Kenya Colony, British East Africa. In the previous year, on a farm in the Rift Valley, a heavy mortality had occurred among ewes and newly born lambs, the death rate in the latter being 95 per cent. At necropsy a focal necrosis of the liver was found. Transmission experiments showed that the etiological agent was a filterable virus. During the course of the investigations the four Europeans engaged in the work all developed a dengue-like syndrome, characterized by rigors, backache, and fever persisting for from twelve to thirty-six hours; native attendants were similarly affected. Goats and cattle were also found susceptible; but though the disease was not contagious there was evidence to suggest that it might be transmitted by a mosquito, probably *Taeniorhynchus brevipalpis*. The virus, preserved in oxalate-carbol-glycerin, was brought to this country by Mr. R. Daubney, and in May of his year was successfully inoculated into two lambs by Major Dalling, M.R.C.V.S., who conducted a necropsy; five and a half days later he became acutely ill with rigors, fever, headache, and backache. His laboratory assistant developed similar symptoms, and later another person presented the same syndrome after a necropsy on an infected lamb.

Dr. Findlay's investigations showed that there was a primary polymorphonuclear leucocytosis followed by a leucopenia during the course of the disease, and that protective antibodies appeared in the serum of those definitely infected as well as in those exposed to sub-infective doses of the virus. Inoculation of filtrate into monkeys had produced similar features, with, as in man, no fatality; the immunity lasted for at least six months. The virus proved highly pathogenic for mice, field voles, wood mice, dormice, and the golden hamster, the death rate varying from 98 to 100 per cent. Rabbits, grey squirrels, guinea-pigs, and several other species of animals proved insusceptible. Infection was successfully transmitted by subcutaneous, intraperitoneal, intratesticular, or intracerebral inoculation, by application to the scarified skin, and by instillation into the nares or conjunctival sac. The pathological changes were found to consist of focal necrosis of the liver or generalized hepatitis, and haemorrhages in various internal organs. Acidophile bodies were found in the liver in certain species of animals, and kariorrhexis of the polymorphonuclear leucocytes was characteristic. Monkeys immune to yellow fever were found to be susceptible to Rift Valley fever, and neither immune yellow fever serum nor dengue immune serum protected mice.

Dr. E. HINDLE, in opening the discussion, stressed the resemblance of this disease to yellow fever and dengue, but pointed out that in yellow fever necrotic lesions involved the mid-zonal cells, whereas in Rift Valley fever the necrosis did not appear to be restricted to any part of the lobule. He was rather sceptical about the significance of the intranuclear inclusion bodies found by Dr. Findlay in mice, as he had found similar bodies in toads and in the livers of London sewer rats; he was disappointed to hear that yellow fever did not confer immunity. Dr. J. T. EDWARDS called attention to the clinical and pathological similarities of Rift Valley fever to the disease known as "three days' sickness," which affected cattle in India, and suggested it would be worth Dr. Findlay's getting the virus from India for purposes of comparison. Mr. R. E. MONTGOMERY said he would like to make a reference which might have some historical significance in the study of this disease. In 1912, when he was at Mombasa, there had been a mortality rate of 90 per cent. among lambs. Two infected lambs were sent down for investigation, and inoculation experiments with other lambs produced fatal results; at necropsy histological lesions similar to those described by Dr. Findlay had been found. Though there was no evidence of infection of human beings then, he thought it was probably the same disease in 1912 as in 1930. Dr. HAMILTON FAIRLEY asked for information on the duration and range of complement-fixation met with in the disease, and also whether Dr. Findlay had made any observations on the blood chemistry of enzootic hepatitis. Experimentally it was known that four-fifths of the liver had to be removed before biochemical changes occurred, but in many of Dr. Findlay's animals the hepatic necrosis was so generalized that it appeared possible that hyperglycaemia and other significant alterations in the plasma might occur. Dr. MANSON-BAHR asked whether cytoplasmic inclusions like Councilmann bodies were indicative of ultra-microscopic virus disease. He was particularly

interested, as many years ago he had described similar bodies in sprue

In reply, Dr. FINDLAY stated that Rift Valley fever fell into the same category as yellow fever and sandfly fever. To date he had not had an opportunity of studying the biochemistry of this disease, but proposed to do so later. Complement-fixing antibodies were found for at least six months after recovery; the amount of complement fixed in their experiments had been 3 M.H.D.'s. He expressed the view that Councilmann bodies had not the same significance as intranuclear inclusion bodies in indicating an ultra-microscopic virus.

PHYSICAL FINDINGS IN PSYCHONEUROSIS

At a meeting of the Medical Society of Individual Psychology, held on December 10th, with Dr. W. LANGDON BROWN in the chair, Dr. F. G. CROOKSHANK read a paper which he described as, though nominally concerned with the physical findings in psychoneurosis, yet really one giving an account of observations made by him during the last two years as a diagnostic physician at the Institute of Medical Psychology (Tavistock Square Clinic). In this capacity he had now had the opportunity of examining several hundreds of new cases.

The routine procedure was for each patient to be accorded a full hour's interview, during which time a pretty complete physical investigation was carried through, while occasion was taken to arrive at a preliminary psychological appreciation of the situation. In carrying out these examinations Dr. Crookshank said he had had, for more than a year past, the advantage of the assistance of a woman colleague (either Dr. Hutton or Dr. Weber, as a rule), and the plan of examining both male and female adult patients, from the physical as well as from the psychological angles, in this conjoint way had proved extremely successful, so far as could be judged. After discussion of many points of anthropological, physiological, morphological, and psychological interest, Dr. Crookshank said he desired to emphasize the great importance, in dealing with "psychological cases," of paying attention to the fine adjustment of the organs of sense—the means of reception by the patient of impressions from the outside world. He (the speaker) was convinced that the complete correction of ophthalmic defect was often of far greater consequence to the "nervous" patient than ophthalmic surgeons were prepared to admit. The frequent advice to migrainous persons that "the defect was too small to call for glasses," or that the "glasses need only be worn when the headaches occurred," was really deplorable. Another point of some interest was the great frequency with which plugging of the ears with wax was found in "nervous" patients, and those complaining of noises in the head, "odd feelings," and so on. Actually, at least one in four seeking help at the clinic had both ears so plugged, either with or without complaint of deafness. A matter of some seriousness was the frequency with which hyperthyroidal states, referable to emotional strain, were found present, without recognition, in patients, male or female, who had been passed by their own or special medical advisers as "without organic disease." The same phrase was constantly applied to patients with severe refraction defect, heavily infected tonsils, carious or defective teeth, gross constipation, and those suffering from the abuse of tea and tobacco. The sooner this wretched and now almost meaningless cliché disappeared the better. A large proportion—perhaps 25 per cent.—of the new cases at the clinic were found to be the subjects of oxaluria. The association of oxaluria with anxiety states and neurasthenias was a matter once better recognized than now; the explanation was not dietetic, but metabolic.

In conclusion, Dr. Crookshank declared that the opportunities he had enjoyed at Tavistock Square had more than strengthened his conviction of the rightness of the individual psychologist's approach to the subject of the psycho-somatic unity. So far as the neurotic patient was concerned, the really important thing, as Adler would say, was not the actual physical defect, organ-inferiority, or stigmata of "degeneration," etc., present in the beginning, but "what the patient did about it." At the same time, the *nature* of the physical defect or inferiority would determine or colour the life-style of the patient who decided upon a neurotic life-line. But physical defect was neither necessary to neurosis nor did it render neurosis inevitable. The case of the psychotic was, however, somewhat different. Whilst he (the speaker) held, with Adler and Wexberg, that the life-style of the psychotic was to be explained in the same way as that of the neurotic, nevertheless the psychotic might be looked upon often, if not always, as one who started with a special biological pattern or outfit. This again by no means implied the necessity for mental breakdown, or excused the adoption of a neurotic life, ending in psychosis. But it did mean that the adoption of certain methods of living was, for those so imperfectly equipped, much more dangerous than for others. An analogy might be attempted. An aviator of experience and skill would say that "crazy flying" might be perfectly safe, given a good machine in good order, but that to attempt "stunts" with certain types of machine, or with one in bad order, would be courting a crash. So with the human being. No imperfection of original equipment compelled or need compel anyone to live wrongly; but it might render the neurotic style of life highly dangerous.

In the discussion which followed, the PRESIDENT pointed out certain ways in which the out-patient department system had undergone improvement. He alluded to a distinction made by Dr. T. A. Ross, in a recent meeting of the Royal Society of Medicine, between the attitude of the psychoneurotic and of the psychotic towards his dyspeptic symptoms. The psychoneurotic would listen to the possibility of a more remote origin, whereas the psychotic would never admit in any way this approach to the subject. Dr. LAURA HUTTON, dealing with the subject of hyperthyroidism, said that in three cases which she had treated psychotherapeutically, the exciting cause had been violent love-making, which had been carried too far, and yet not far enough—namely, to completion. In two of the cases the flushing associated with the hyperthyroidism had resulted in the establishment of a vicious circle.

Dr. HILDA WEBER indicated certain ways in which the examination of the hands was of importance. It was of interest that it was less the movements of which the hands were capable than the use man made of them which was of importance. The extent of the hand area in the cerebral cortex was an example of interaction between function and structure. Dr. O. H. WOODCOCK gave a clinical example of dyspepsia of psychological origin occurring in a psychotic. This case had exemplified the "fixity" referred to by the president. Dr. ERNEST GRIFFEN had noticed that ridges on the nails were associated with ill-health. He pointed out that certain specialists were apt to mete out the same kind of treatment to the patients sent to them.

Dr. J. R. REES, in answer to a question, said that at the Institute of Medical Psychology it was the practice to see relatives, but not as a routine measure. He had been intrigued by the differentiation made by previous speakers between psychoneurotics and psychotics. Dr. E. A. BENNETT doubted whether coitus interruptus was such an important factor in the causation of anxiety neurosis as some authorities supposed. Dr. BEVAN BROWN

agreed with Dr. Crookshank that in many cases the use of liquid paraffin as a laxative was harmful. In his experience many hysterics refused to discuss the possibility of a mental cause of their dyspepsia. He thought that frustrated sex desire was a potent cause of hyperthyroidism.

Dr. CROOKSHANK, in replying, pointed out that tight collars in men, and badly fitting boots and shoes in women, were a potent cause of ill-health, which reacted unfavourably upon the mental condition. He agreed with Dr. Hutton's conclusions as to the effect of emotion as a factor in the causation of hyperthyroidism. He had found that there was a greater tendency for psychosis to be accompanied by physical imperfections than was the case with psychoneurosis. Loss of sex desire following a gynaecological operation not involving the ovaries was often psychologically determined and amenable to psychotherapy. With regard to coitus interruptus and its effects, it was well to refrain from generalizations; in some instances it might be the expression of a neurosis. He considered that the beliefs of the hysterics were not held with the same tenacity as was the case with the psychotics.

ANAEMIA AND POLYCYTHAEMIA

At a meeting of the Pathological Society of Manchester, on December 9th, Professor A. E. BOYCOTT delivered an address on anaemia and polycythaemia.

Professor Boycott said that polycythaemias fell into two classes—the apparent and the real. Apparent polycythaemias were due to a lack of plasma and a concentration of the blood. They occurred in newborn children (when it was necessary for the child to be as small as possible, and when the viscosity of the blood was of little or no importance), in cholera, and in secondary shock. Since the maintenance of an adequate circulation depended on the proper filling of the right heart, any substantial diminution of blood volume was incompatible with life for more than a few hours. Locally, a polycythaemia might be produced by cutting down the oxygen supply of the capillary endothelium (for example, by constricting the finger); plasma at once leaked out and erroneous blood counts were obtained. Real polycythaemias were found (*a*) in deficient oxygen supply, or (*b*) in splenomegalic polycythaemia. The best known was that which occurred at high altitudes. Various fantastic explanations of the phenomenon were given in early days, but it was certain now that it was due to a compensating action by the bone marrow, which increased the concentration of haemoglobin in the circulating blood without enlarging the blood volume. This was first shown clearly in animal experiments; afterwards, by Haldane and Douglas in man. Anything which interfered with the due supply of oxygen could lead to the same result—chronic tracheal or bronchial obstruction, pneumothorax, chronic carbon monoxide poisoning, and many examples of congenital cardiac defect. The ordinary case of heart failure seldom showed any degree of polycythaemia, and the patient was often slightly anaemic; he was short enough of oxygen, but had enough difficulties to face in maintaining arterial pressure and control over the distribution of blood without adding to the work of the heart by a raised viscosity of the blood. Peculiar interest attached to the demonstration by Doyon and Morel, and later by Campbell, that excess of oxygen led to anaemia. The facts showed pretty clearly that what was known as the "normal" level of haemoglobin was determined by the pressure of oxygen in the atmosphere in which one happened to live. What was "normal" in Manchester was mild anaemia in Johannesburg, and the nations of the Andes had a "normal" haemoglobin percentage of 145. With any given oxygen supply the body evidently struck the balance between oxygen-carrying power and viscosity, and the polycythaemia of high altitudes soon disappeared on returning to sea-level. Professor Boycott said that in splenomegalic polycythaemia there was no demonstrable difficulty about the oxygen supply, and the production of red cells by the marrow was causeless—that is, the disease was a tumour of red corpuscles. The body protected itself so far as it could by increasing the volume of the blood, so that at any rate the blood was not solid and there was some plasma: in the end the heart generally failed from having to pump round such viscous fluid. The precise level of haemoglobin appropriate to life at about sea-level in this country had lately been investigated carefully by Dr. Price-Jones. He found an average normal figure for men of 105 per cent. on the Haldane scale and for women of 98 per cent.; these figures were higher than the standards fixed thirty years ago, but lower than the 112 or 114 per cent. which had been determined by several observers in America. He had shown that this difference was not due to technique, but was inclined to attribute it to slight chronic carbon monoxide poisoning due to habitual and persistent use of closed motor cars. The variability of the percentage of haemoglobin was not large, some 4 per cent., which was about the same as the variability of stature in a homogeneous population. Its relationship to marrow activity was very precise: a rise in haemoglobin immediately lowered the proportion of reticulocytes in the circulating blood and a fall stimulated their production.

TREATMENT OF EMPYEMA

At the December meeting of the Section of Medicine of the Royal Academy of Medicine in Ireland Dr. GEOFFREY BEWLEY reported the case of a woman, aged 58, who was admitted to hospital in October, 1929, with a right-sided empyema following what appeared to be an attack of pneumonia.

Pus was obtained on exploratory puncture, but operation was postponed owing to the large quantity of purulent sputum brought up. Pneumococcal pus and gas were obtained in a later puncture, and *x* rays revealed a gas-containing empyema. Operation was again postponed in the hopes of the sputum diminishing. Exploration was negative on two subsequent occasions. Clinically and radiologically the empyema showed signs of complete healing, and in January, 1930, the woman left hospital apparently well. In June she returned with signs of an abscess in the left lung, and a radiogram showed an abscess full of fluid in the left lower lobe, and another abscess cavity at the base of the right lung. The empyema had disappeared completely. Treatment by postural drainage was tried with success, and she was able to leave hospital in eight weeks. From that time onwards her condition had been very good, and she had had no cough. An *x* ray taken a year later showed that the cavity in the left lung had disappeared, and that the one in the right lung was smaller.

The chairman (Dr. A. R. PARSONS) thought that in many cases abscess of the lung following operation was due to the introduction of tubes into the mouth and throat during anaesthesia. He realized that some cases were haematogenous in origin. Many patients recovered under medical treatment, and operation should be deferred as long as possible. Dr. T. M. CORBET said that he had recently seen two cases of pneumococcal empyema in brothers. The parents refused to allow operation in each case, but the pus gradually seemed to disappear. Much thickening and pulmonary fibrosis were left, and he felt that both patients would be physically defective throughout life. All such cases should be operated on. Dr. E. T. FREEMAN thought that the empyema in Dr. Bewley's case must have followed the rupture of an abscess into the pleural cavity, as only in that way could the presence of air be accounted for. He felt that pneumococcal

empyemata should be operated on, but streptococcal ones should be left until there was no possibility of the lung collapsing when the opening was made. Dr. H. QUINLAN referred to seven cases of abscess of the lung which had been under his care during the last two years. Many cases of empyema resulted from the rupture of pulmonary abscesses into the pleural cavity. Dr. V. M. SYNGE said he did not regard postural drainage as an efficacious method of treatment. It was very uncomfortable for the patient, and he had never seen any good result follow it. He thought it was wrong to be too expectant in the treatment of these cases. During the last four years he had had seven cases of abscess of the lung, one following tonsillectomy, two following pneumonia, two following septic emboli, and two following the aspiration of a foreign body. In one case the patient had had treatment with an autogenous vaccine, but had subsequently died from an empyema. In other cases he had tried artificial pneumothorax, but complete pneumothorax was difficult to obtain as a rule owing to the presence of adhesions. He felt that in chronic cases which did not respond to expectant treatment operative treatment should be carried out.

Dr. J. MOWBRAY said that he was strongly in favour of early operative treatment, as against postural treatment. Dr. R. H. MICKS referred to a case in which a surgeon opened the thorax, broke down pleural adhesions, and squeezed with his hand the lower lobe of the lung, in which there was an abscess. The patient did well, but he (Dr. Micks) could not recommend such drastic treatment. Dr. J. O'CONNOR mentioned two cases of pneumococcal empyema in children which had cleared up by repeated aspirations. He thought this method was well worth trying in children.

Dr. BEWLEY, in reply, described his method of carrying out postural drainage, and said he had no doubt that in some cases, as in the one he had described that evening, it was very efficacious. It was sometimes most difficult to decide on the source of gas in an empyema. He thought that if improvement did not take place after postural drainage all cases should be operated on or repeatedly aspirated, as much pus as possible being taken away. He agreed with Dr. Freeman that a streptococcal empyema should not be operated on too early. If operation was done before the adhesions were firm there was the possibility that a localized empyema would become generalized, with the probability of a fatal result.

At the December meeting of the Manchester Medical Society, with Professor J. S. B. STOPFORD in the chair, Dr. F. M. R. WALSHE read a paper on the treatment of some common nervous diseases. Dr. Walshe began by referring to the somewhat unhealthy luxuriance of the therapeutic tree, and to the need in which it stood of pruning. He dealt with some of the difficulties that arose in long-standing chronic nervous diseases in preventing the patient and his family from having recourse to futile and even dangerous modes of treatment. Of the common modes of treatment in favour for the relief and cure of nervous diseases, he referred to electrotherapy and to massage and to the benefits that might be expected from their employment, emphasizing the extremely narrow sphere of usefulness of the former. In discussing the treatment of disseminated sclerosis, he emphasized the value of rest, and pointed out that the characteristically fluctuating course of the malady made the assessment of any particular form of treatment extremely difficult. He had seen no good results from protein shock therapy, from liver diet, or from the recently described "vaccine" treatment. Some points in the care and treatment of other common nervous diseases were then discussed.

Reviews

MODERN MEDICAL TREATMENT

The appearance in two goodly volumes of a book on *Modern Medical Treatment*,[1] by Dr. E. BELLINGHAM-SMITH and Dr. ANTHONY FEILING, forcibly reminds one of the rapid development of this subject. Modern scientific medicine has often been accused of paying but indifferent attention to treatment, and there has been some justification for that charge. Too often in the recent past one found in a textbook a full and elaborate discussion of the etiology, pathology, signs and symptoms, and diagnosis of a disease, followed by a perfunctory paragraph on treatment, such as this: "Arsenic and iron should be given, bromide is often useful, and ergot has been recommended. A nourishing diet is essential, and careful attention should be paid to the bowels." It is no exaggeration to say that this was often the only help that was offered to the student in an essential part of his work. It is not surprising that in consequence he paid little attention to the treatment sheet of patients in hospital, and often did not know the ingredients of the mixtures in his hospital pharmacopoeia. To such a student initiation into practice brought a rude awakening; he found that the stone that the builders had rejected had become the head stone of the corner. In his brief but charming and erudite introduction to the book before us Sir Humphry Rolleston quotes with approval the dictum that the three most important things in medicine are diagnosis, diagnosis, and again diagnosis. Undoubtedly this is the rock on which scientific medicine must be built, but the saying has often been taken too literally. Successful treatment can only be based on correct diagnosis, but it is such treatment which is the goal of the art of medicine.

Rather more than thirty years ago Burney Yeo's book on treatment was the standby of the student and house-physician, and the present work reminds us of it in many ways. Comparing the two books, we are immediately struck with the enormously increased range of our methods in treatment since the publication of the earlier one. It is not merely that many new drugs have been introduced and a considerable number of old ones discarded; the whole basis of treatment has been widened. We once heard a physician assert that the treatment of a medical case in hospital could be summed up as "good food and nursing, with something three times a day out of a bottle." Such a physician would find himself somewhat at a loss in the wards of a modern hospital. Physical methods, such as massage, systematized exercises, heliotherapy, actinotherapy, and treatment by open air, were almost completely neglected last century. In this respect we have, as Sir Humphry Rolleston reminds us, returned to the practice of the ancient Greeks in resorting to Nature's own methods. Hydrology, which for centuries was composed largely of magic and faith, is being put on a more scientific basis. Electrotherapy, until the last quarter of the nineteenth century, was regarded as dangerously akin to quackery. Entirely new laboratory discoveries, such as endocrines, vitamins, antigens, and antitoxins, have found practical applications. And last, but by no means least, there is a much livelier appreciation of the necessity for regarding the patient as an individual who is reacting in a particular way to some disturbance in his external or internal environment; a realization that his symptoms are produced by altered reflexes which cause his "disease."

[1] *Modern Medical Treatment*. By E. Bellingham-Smith, M.D., F.R.C.P., and Anthony Feiling, M.D., F.R.C.P. With an introduction by Sir Humphry Rolleston, Bart., G.C.V.O., K.C.B. Vols. i and ii. London: Cassell and Co., Ltd. 1931. (Vol. i, pp. xvii + 701; vol. ii, pp. viii + 758. 30s. net the two volumes.)

These alterations in his reflexes may be produced at the highest level of the nervous system—that is, the psychical level—and can only be dealt with by psychotherapy.

This does not mean that we have come to place less reliance on drugs. It is a curious fact that scepticism as to the value of drugs corresponded more or less to the most materialistic phase of natural science. We may attribute some of the return of belief in drugs to the discovery of hormones and vitamins, since these showed how largely the body was normally influenced by small quantities of active chemical substances. The history of treatment by drugs affords an interesting example of the interweaving of art and science in medicine. The use of many drugs was discovered empirically, and the scientific explanation of their action was not arrived at till long after, while in some cases it is still to seek. Others have been discovered by deliberate pharmacological research based on animal experiment.

The book before us well illustrates all these general considerations. It is interestingly written from a modern point of view, while conserving methods which long experience has proved of value. Newer methods have not been recommended without personal trial by the authors. If a method has been tried and found wanting they do not hesitate to say so. The feeling that the work throughout is the expression of personal experience adds greatly to its value. We are only inclined to disagree with two statements. We do not prefer bromide to luminal in the treatment of epilepsy, and we should attach more importance to the withdrawal of alcohol as a factor in producing delirium tremens. As a corollary to this we should not attempt to "taper" a chronic alcoholic nearly so rapidly as the authors suggest. With the rest we are in cordial agreement, and we can emphatically recommend a work characterized throughout by sanity and breadth of vision.

URTICARIA AND ITS CONGENERS

Since the fundamental observations of Widal on the phenomena of anaphylactic shock, much attention has been paid by French workers to the problem of the etiology and treatment of urticaria and allied conditions, most of which may be described as manifestations of allergy. Among the most prominent of these observers is Dr. P. VALLERY-RADOT, who has published within a short period two monographs, one on Specific Hypersensibility in Skin Diseases[2] (with Mademoiselle V. HEIMANN), and a second on the Phenomena of Shock in Urticaria[3] (with Dr. L. ROUQUÈS). He maintains that the essential basis of specific hypersensibility (of which urticaria is the classical example) is the possession of the colloidoclasic diathesis—another way of saying that the colloids of the plasma are unstable. Consequently, in certain circumstances such as the meeting of antigen with antibody, the sudden introduction of some particular protein or crystalloid body into the stream of circulation, or the exposure to physical fatigue, cold, or the influence of emotion, the haemoclasic crisis is precipitated.

The *provenance* of the colloidoclasic diathesis still remains entirely obscure: it may be congenital, and therefore possibly hereditary in origin, or it may arise gradually or quite suddenly at any epoch in life; and whether the liver, the thyroid, or some other endocrine gland is the seat of the crime not even the author can say. The most prominent clinical manifestations of the haemoclasic crises are threefold—fall in blood pressure, leucopenia, and increase in the blood coagulation time. Of all the cutaneous phenomena associated with this state urticaria is the most striking and typical. There are other dermatoses such as drug eruptions, and certain types of eczema, erythema, or even erythrodermia, which, although extremely diverse morphologically, may be cited as colloidoclasic accompaniments; but all are agreed that urticaria is the classical cutaneous manifestation of allergy, and doubtless that is why M. Pasteur Vallery-Radot has devoted a whole volume to its discussion.

All the well-known types of urticaria are dealt with, not only the banal alimentary form, but also those resulting from the effects of drugs, fatigue, cold, emotion, etc. Nor does he shirk the thorny problem of treatment. The various modern methods of "skeptophylaxis," the production of a temporary immunity to anaphylaxis—as by the administration of small doses of the peccant antigens at appropriate moments and by appropriate paths—are all reviewed and criticized, and, in some instances, brilliant therapeutic results are recorded. The author discusses also the methods of producing a permanent change in the body fluids (*modification humorale durable*), which is much the same as protein shock medication. Among these methods are included auto-haemotherapy, auto-serotherapy, peptone injections, and injection of various chemical compounds, such as magnesium hyposulphite, calcium chloride, sodium bicarbonate, and caesium eosinate. They all have their advocates, but it cannot yet be said that the problem of allergy in general, or of urticaria in particular, approaches solution. The present position of the subject, however, and the lines upon which the problem is being tackled, are well recapitulated in these two volumes, while they will be found well worthy of study by dermatologists and others interested in that important department of medicine which deals with the manifold phenomena of allergy.

OPERATIVE SURGERY

The American editor (Dr. I. S. RADVIN of Philadelphia) of Professor MARTIN KIRSCHNER'S *Operative Surgery: General and Special Considerations*,[4] tells us that it is a translation based upon the first German edition, with a number of new illustrations and additions generously provided by the author. As he justly remarks, the illustrations, for the most part in colour, are so excellent that very little is left to the reader's imagination. This volume is more concerned with general considerations and the general principles of surgical treatment, than with specific maladies or injuries in special parts of the body. The subject-matter is divided into eleven chapters, from the titles of which some idea may be obtained of what is included and excluded. Chapter I deals with the operator and his assistants, the general examination and management of the patient, a very full discussion of his general care and preparation for operation, and many minutiae, some of which are usually included under the heading of minor surgery. As regards the early rousing of patients, a subject which has recently been much discussed in the press of this country, Professor Kirschner's dictum is of interest. He says:

"The custom of early cleaning of the wards should be abolished, since it disturbs the patients. Nor should it be necessary to disturb the entire ward early in the morning to say this even though I begin to operate before 7 o'clock in the morning."

Abdominal operations are considered only in very general terms, but nerve, bone, joint, and muscle surgery

[4] *Operative Surgery: General and Special Considerations.* By Dr. Martin Kirschner. Authorized translation by I. S. Ravdin, B.S., M.D. London: J. B. Lippincott Company. 1931. (Pp. xii + 961; 746 figures. 50s. net.)

and vascular surgery are treated separately, as is plastic surgery. There is a special well-illustrated chapter on amputations, in which the author, to our mind, gives too great importance to "fancy" procedures, such as kinematization, which the post-war experience in this country has considerably discredited as practical measures. Nor do we think it was worth while to devote a whole-page coloured illustration to an operation for varicose veins which the author labels "very rarely done."

We cannot overpraise what is included in this book, much of which will not be found in other works on the subject. At the same time, much is omitted which one expects to find under so comprehensive a title. Great care has been taken to describe all the details of the procedures recommended, whether they are major or minor proceedings. Surgery conducted on the author's principles and as directed by him will obviously demand a very fully equipped hospital and a well-trained staff of nurses and assistants. This is not the operative surgery for a cottage hospital; but, all the same, perfection may be aspired to even if it be unattainable.

A GUIDE TO INCOME TAX

Correspondents on income tax matters not infrequently ask to be referred to some simple but helpful textbook, and their need bids fair to be met by a recent publication, *Income Tax and the Professional Man (including Sur-Tax)*,[5] by Mr. K. A. COLES. This little book has been written by a man who evidently has the advantage of a practical acquaintance with the subject, and it is well arranged and clearly printed. It has been published since the passing of the second Finance Act of 1931, and is therefore completely up to date. Any adverse criticism we have to make is limited to a few minor points. Mr. Coles's remark, on page xii, that the assessor of taxes "can be neglected for all practical purposes" may be true in some localities, but recent press correspondence suggests that the assessor's functions are often by no means negligible. The paragraphs dealing with the non-allowance of capital expenditure are clearly written, but some prominence might with advantage have been given to the fact that improvements to existing professional equipment rank as capital, though this aspect of the matter is given more attention in the section dealing with renewals and replacements. We endorse Mr. Coles's opinion (p. 22) that the wear-and-tear plus obsolescence allowances are preferable to the replacement allowance; our Queries and Answers column has often contained advice to the same effect. The wear-and-tear rates given in Table II are perhaps somewhat misleading as regards motor cars, for which the rate is stated as being 20 per cent. for 1931–32, and 20 per cent. plus 10 per cent. for 1932–33. In some areas the district commissioners allow 15 per cent. only, unless there is exceptionally heavy use of the car, and the 10 per cent. addition for 1932–33 is —as indeed the author implies in another part of the book—10 per cent. of the existing rates, so that the rates for 1931–32 and 1932–33 are really 15 per cent. or 20 per cent. and 16½ per cent. or 22 per cent. respectively. The book covers a fairly wide field, including the special points arising in connexion with partnerships, employments, etc., Schedule A assessments, and sur-tax, and Mr. Coles has made a successful attempt to present his explanations without using technical language where simple phraseology will serve the purpose. The section dealing with medical profits and expenses is well written, and the example setting out a specimen account and computation will be found very helpful. It is a handbook which we can confidently recommend to medical practitioners.

[5] *Income Tax and the Professional Man (including Sur-Tax).* By K. Adlard Coles, M.A., A.C.A. London: Crosby Lockwood and Son. 1931. (Pp. xiii + 100. 4s. 6d. net.)

EDWARD JENNER

Those discerning readers who have succumbed to the charm of Dr. DAWTREY DREWITT'S *Romance of the Apothecaries' Garden*, and his more recent *Jenner's Note Book*, will turn with pleasurable anticipation to his *Life of Edward Jenner*.[6] Sharing with Jenner a love of the country and natural history, Dr. Drewitt writes with just that suggestion of classical lore that is attractive rather than awe-inspiring. As a result his account of a country practitioner who was "destined to save more lives than the wars which raged during his lifetime had destroyed" compels attention from start to finish. Jenner, when working at medicine at St. George's Hospital, was offered the appointment of naturalist on Captain Cook's expedition, and also a partnership with John Hunter, but being devoid of the ordinary forms of ambition he preferred to return, in 1773, to the meadows and hills of the Vale of Berkeley and the practice of medicine, lightened by the observation of natural history and the composition of occasional verse. Sixteen years later he wrote the attractive chapter on his observations as a naturalist, especially those on the predatory habits of the cuckoo. When a medical student Jenner heard and never forgot the remark of a young woman at Sodbury: "I cannot take small-pox, for I have had cow-pox"; how in after years this bore fruit Dr. Drewitt describes, and in vigorously indignant terms he writes of Charles Creighton's campaign against Jenner and vaccination.

VERTEBRATE ZOOLOGY AND LITERATURE

The Blacker Library of Zoology has just issued an important *Introduction to the Literature of Vertebrate Zoology*,[7] in a volume of some 650 pages. It is divided into three parts. The first gives a general account of the history of vertebrate zoology from the earliest times. Particular attention is paid to literature, of course, but brief descriptions are also given of natural history societies, museums, and zoological stations, travelogues of naturalists, illustrations and animal drawings, and so on. This is the section which will have the most general appeal —especially to medical men, from whose ranks so many natural historians have been drawn. The second part deals with the literature of McGill libraries, in both a chronological and a geographical order to facilitate reference to subjects. The third and largest part is a partially annotated catalogue of the vertebrate items in the various libraries in the University. The volume is excellently produced, and will have a value in all libraries as a source of references to vertebrate zoology, and McGill University is to be congratulated on its appearance.

NOTES ON BOOKS

Since so many of the difficulties in adult life which have a psychological basis are traceable to faulty upbringing in childhood, Dr. ALICE HUTCHISON'S book *Motives of Conduct in Children*[8] will be very welcome to parents, and also to medical practitioners, who are so often confronted by such mental or moral abnormalities as stammering, habit spasms, bed-wetting, nail-biting, fits, and night terrors. Her treatment of these and other topics, though brief, is practical, indications being given of the various causes, with illustrations of the most hopeful lines of treatment. It is often the case that children are left alone to struggle

[7] *An Introduction to the Literature of Vertebrate Zoology.* Compiled and edited by Casey A. Wood, M.D., LL.D. London: Milford, Oxford University Press. 1931. (Pp. xix + 643; 1 plate. £3 3s. net.)

[8] *Motives of Conduct in Children.* By Dr. Alice Hutchison. With foreword by Dr. Cyril Burt. London: Jarrolds, Ltd. 1931. (Pp. 185. 6s. net.)

out of such difficulties for themselves, but, as Professor CYRIL BURT points out in a foreword, such struggles, apart from the unhappiness they induce at the time, may often leave in their train a distorted and warped mind. Considerable attention is paid by the author to sex evolution and instruction, and the serious problem of the backward child is dealt with in a way that indicates long experience. The book meets a real need, and the simplicity of the language employed reveals clearly the psychological problems which are involved in many of these cases.

Specific Changes in the Blood Serum[9] by Dr. S. G. T. BENDIEN of Zeist, translated by Dr. A. Piney, has just been published by Messrs. Heinemann. Its subtitle is "A contribution to the serological diagnosis of cancer and tuberculosis."

Economic Biology[10] (Part II), by PHILIPPA C. ESDAILE, supplies some definite information about the origin, properties, and uses of a number of products likely to come under the notice of students of social science, such as leather, fur, hair, dyes, gums, fibres, and beverages. The material is enlivened by references to ancient history, by plentiful illustration, and by the provision of a useful glossary and index. A brief account of the first part of the work was given in the *Journal* of June 2nd, 1928.

Englishmen at Rest and Play[11] is written by some members of Wadham College, Oxford, and is edited by Mr. REGINALD LENNARD. It deals with English watering places; the observance of Sunday; country inns and alehouses; meals and meal-times—subjects connected more or less directly with medicine, but treated from a non-medical point of view. So non-medical, indeed, that it sometimes appears as if the writers were not fully acquainted with the renown of the doctors of their own university. Mr. Lennard, for instance, speaks more than once of Dr. Walter Bailey as one of the Queen's physicians. His real title to fame was that he was regius professor of physic, was in orders, and was a Fellow of New College, where, as his tombstone still shows, he lies buried in the ante-chapel. In like manner it is hardly fair to say "Richard Lower of Christ Church, Oxford, who was assistant to a physician named Thomas Willis." Both were so eminent in their own spheres that their names are known to every anatomist throughout the world. For some reason barbers have always been at loggerheads with the community. At first with the Church because they persisted in shaving on Sundays, and with their town councils because they kept disorderly houses or left their bowls of blood in their shop windows to the scandal and offence of passers-by. Even in our own days, regulations under D.O.R.A. have been enacted to control their business. It has long been known that in Edinburgh the masters of the craft of barber surgeons had the sole right of making and selling aqua vitae, but Dr. Brethorton is able to show that in England, at least in one instance, surgeons were engaged in the trade. The record runs: "James Careless petitioned my Lord Bishop [of Worcester] for a licence to sell ale because he was a surgeon and had many patients come to him for help and found it a great inconvenience for them to go to remote places for their diet and drink, and in that respect obtained a licence with a limitation to sell ale to none but his patients. But now he far exceeds his bounds and entertains all comers as well by night as by day, high and low, rich and poor, beggars and all, none excepted." It might also have been mentioned that the matron of St. Bartholomew's Hospital in London had permission to have a cellar under her lodgings, and to sell beer to the patients of a better quality than that provided by the governors.

PREPARATIONS AND APPLIANCES

SVEN JOHANSSON'S INSTRUMENTS FOR KIRSCHNER WIRE

Mr. W. G. OGILVIE, F.R.C.S., writes:

The use of fine piano wire in the treatment of fractures by skeletal traction was originated by Kirschner of Tübingen. The advantage of wire over metal pins lies in its fineness. It can be introduced under local anaesthesia without causing discomfort, while the small punctures in the skin minimize the risks of sepsis during treatment, and are healed within a few days of withdrawal. The fineness of the wire, however, demands more elaborate apparatus for introduction and traction than is required with pins. The drill must grip the wire firmly, give it a high rotary speed, and support its whole length against "whip" while it is being driven through the limb. The traction apparatus must include some device for rendering the wire taut, so that it remains straight and rigid during traction. Since the advent of the Kirschner wire many forms of drill and calliper have been designed. The drills are for the most part expensive, elaborate, and require constant attention. The traction callipers depend upon some accessory tool, jack, spanner, or tommy bar for stretching the wire. The most simple, and at the same time satisfactory, apparatus which I have seen is that of Dr. Sven Johansson of Gothenburg.

The drill is of the Archimedean type, but the sliding collar carries a self-reversing ratchet, so that a continuous rotary movement in a clockwise direction is imparted to the wire. In place of a chuck it has a small nipple, with a slot on its summit. One end of the wire is flattened to fit this slot, the other bears a triangular point. Support is given to the wire by a three-piece telescopic extension ending in a convex shell. In use the flattened end of the wire is pushed into the slot in the nipple, the telescope is drawn out till the shield is flush with the pointed end of the wire, the shield is pressed gently against the skin at a point previously rendered anaesthetic, and the wire is quickly driven through the soft tissues and bone by a few rapid strokes on the travelling collar.

The traction calliper consists of two stout bracket-shaped bars, hinged at their middle. Each bar is slotted at one end, and in the slot rotates a small eccentric with serrated edges actuated by a thumb lever. The ends of the wire are passed through these slots and jammed between the serrations on the eccentric and the base of the slot. The levers working the eccentrics are locked by loops of wire sliding along the bars. The opposite ends of the side bars are joined by a threaded bolt; by turning a wing nut on one end of this bolt the ends are approximated and the further ends separated, putting the wire taut. A ring, travelling on the bolt between the two bars and bearing a hook for the traction cord, can be adjusted to lie at the mid-point of the calliper.

A smaller calliper, in the form of a V hinged at its centre, is made for traction in the upper limb. The wire is passed through holes in the ends of the side bars and fixed by small thumb screws. The limbs of the V are held apart by a telescopic crutch, resting at each end in notches on the inner edges of the side bars. By turning a nut on one member of the crutch its length is increased and the bars separated, thus tightening the wire.

These instruments have been designed by Dr. Sven Johansson of the Allmanna Sjukhuset at Gothenburg, are manufactured in Sweden by Axel Ericsson. They are supplied in England by Down Bros. of St. Thomas's Street, London, S.E.1

British Medical Journal

SATURDAY, DECEMBER 26th, 1931

WINTER BY THE SEA

t is known that there have been dwellers on the sea-hore from the earliest times The signs of their occupa-ion are still visible on the south coast of England, from he cliff ledges of Hastings to Kent's Cavern on Tor Bay Whether the men of those days roamed at large in the ummer and retired to their caves only in winter it is ard to say. But there are still in many places andering families, like the "tinkers" in Scotland, ho always go into winter quarters in caves by the sea n open-air life has inured them to the wind and eather of the northern climate , but, when the days norten, the stress of the season obliges even these hardy eople to seek out warm corners of the coast, which, wing to the peculiarity of the British climate in winter, ave nearly the same temperature in the far north as on ie south coast There is evidence that men, like birds id animals, have always availed themselves of the sea-iores for shelter against the severities of winter. ivilization has not diminished but rather enhanced ie value of the coast in winter as well as in summer , a means of health and well-being to crowded city opulations The seaside is the place of choice for con-alescent homes and hospitals, and science, a little late the day, is now substantiating the medical values of ght and airs

Recent discussions on the influence of marine climates[1] ve done something to define the indications of the a coast for purposes of health For many years it is been recognized that sea air and sunlight improve e resistance and restore the health of tuberculous ildren, and equally good results are now reported om systematic treatment of the same kind of large mbers of non-tuberculous children showing a variety symptoms, such as recurrent catarrhs and defects of itrition There is general agreement that a change to e coast is contraindicated in all severe and acute ases of disease, but it is claimed, and substantiated precise evidence, that a variety of subacute and ronic disturbances of health, particularly in children, e favourably influenced by a combination of stimulant ipressions at the seaside The reactions of children der marine treatment have now been further analysed d graphically exhibited, and the combined result of e complex of physical impressions is described as a neral *alterant* modification of the entire organism

This conception of the value of the sea has been rried further at the discussion at Amsterdam It is ognized that, apart from these reactions in children, other series of reactions is often observed on the coast in middle-aged and elderly people It is believed that these are characteristic especially of oceanic climates like that of the west and south coasts of Britain. In short, the sea has one action for the young and a different action for the old. The former is a stimulant influence, bringing about an all-round increase of functional activity This is, within bounds, a rational objective for many feeble children who are free from organic disease, as well as for older persons convalescent from illness or operation, or making headway against a slow and chronic infective process On the other hand, in the second category of patients—those who fail in health in later life—the recourse to a marine climate is appropriate mainly in winter, and the climatic influence should be, on the balance, sedative The equable warmth and shelter of the coast conserves and economizes the natural powers of the body instead of calling them forth, maintains the body heat, and reduces the demands on metabolism, excretion, and circulation. It is held that the physical influences in climate appropriate for children—that is to say, for the evolutionary period of life—are external cold, dryness of atmosphere, and wind, all predisposing to exercise , and that the proper influences for mature age and the dissolutionary period of life are external warmth, humidity and a calm air, predisposing to rest and sleep Hence the ideal period for tonic treatment and for children is the summer, when external warmth may be tempered and alternated with cold, and the best period for sedative treatment, and for those in failing health, is the winter, when external cold can be tempered and alternated with heat

Making all allowance for the pitfalls of facile generalization, it is hard to deny a serious significance in this line of reasoning Age and the seasons profoundly modify the characters of disease There must be differences of objective in the treatment employed in the chronic ailments and diseases of the young and of the old The physiological pace may be accelerated or slackened, and often in later life the chief medical endeavour must be to allay functional disturbance, so as to retard organic changes In the statement printed in full in our last issue at page 1151, dealing with the British winter sea-coast resorts, attention has been called to the powerful influence of the Atlantic which gives to these islands a warmth much greater than is proper to their latitude The winters on the south and west coasts are for this reason far more equable than in Southern countries Such an uncommon equability of temperature as that of the western winter would be impossible but for the clouds which give warmth to the nights We are told that the records of bright sunshine on the south coast of England average a little more than two and a half hours a day from November to March, and that this figure does not express the large measure of the daylight and luminosity on the coast "A dry atmosphere is sometimes of medical value but it is also true that the more humid British winter resorts are very favourable to the preservation and restoration of health."

[1] The Treatment of Delicate Non-tuberculous Children at the Seaside, *British Medical Journal*, August 8th 1931 p 268 August 22nd, p 331 The Reactions to Marine Treatment. International Society of Medical Hydrology Amsterdam To be reported in *Int Med Hydrol*, January, 1932.

Many of the advantages of wintering abroad can undoubtedly be obtained in our own country. Sheltered winter resorts exist in great variety on the British coast, and it is too true that their natural advantages and medical value are little recognized by medical men and even by the localities themselves. The present seems the unique opportunity for their wise development and use. The medical case for climatic treatment has often been made before, but never perhaps has a statement appeared showing more clearly the physiological foundation upon which it rests, and the precise evidence of its value in a wide range of incipient and chronic disease. But it is necessary to point out that no medical pronouncement can provide a health resort with the equipment necessary for the recuperation of jaded minds and bodies. If these medical and national advantages are to be realized the localities on the coast must, severally and jointly, assume the responsibility. Co-operation of all the interests involved, organization and co-ordination of effort, a wide circulation of authorized information, scientific propaganda, are all necessary if the age-long instinct is to be gratified, and young and old are to find health and happiness at the seaside.

THE BRITISH POST-GRADUATE MEDICAL SCHOOL

On another page we publish the "statement of progress" issued a few days ago by the newly appointed Governing Body of the British Post-Graduate Medical School. This recapitulates the course of events from April, 1930, to December, 1931, and carries the story beyond the point at which we left it last week, when we announced that applications were invited for the post of dean of the school.

Readers will learn with satisfaction that both the Government and the London County Council are convinced of the necessity for proceeding at once with the scheme for a central post-graduate hospital and school to which they had pledged their support in happier times. The Government, it is true, has felt obliged to reduce to £100,000 the sum of £250,000 originally promised out of public money for building and equipping the school; but the London County Council, despite the economic troubles of to-day, has undertaken to help in bringing the scheme into practical operation by expending a capital sum of £100,000 on the development and adaptation of the Hammersmith Hospital in readiness for its forthcoming association with the school. We welcome this enlightened decision not to defer the establishment, under the auspices of the London County Council and the University of London and with financial aid from the Government, of a real post-graduate hospital and medical college which will be worthy of the metropolis of the British Empire. Stringent economy is the order of the day; but this (to quote a phrase from the official statement of progress) is "an indispensable health service," and as such its organization must be pressed forward.

The general aim of the British Post-Graduate Medical School is to provide, and arrange the provision of, new and extended facilities for the further education of medical practitioners, and to promote the advancement of knowledge of the best methods of treatment of the sick, and the improved application of such methods. Subject to compliance with the statutes of the university, it will be a recognized school of the University of London. In addition to his other duties, the dean of the school will be required to hold a part-time post on the teaching staff, and will be a member of the School Council to be appointed by the Governing Body to advise it on academic matters and questions of educational policy. His inclusive salary will be £1,800 a year. The dean will be the principal executive officer and secretary of the Governing Body, responsible under its direction for arranging courses of instruction for students at the hospital and school, and their attendance at courses elsewhere; for the administrative and financial management of the school; for organizing the supply of information about the school and its work both in this country and abroad; and generally for advancing the aims and purposes of the school. He will attend the meetings of the Governing Body and its committees, and act as the medium of communication between it and other persons in all matters relating to the school.

When in April, 1930, Mr. Arthur Greenwood, as Minister of Health, promised Government support for the establishment of a post-graduate centre at Hammersmith, we said that an appointment vital to the success of the whole scheme was that of the dean of the school. That the Governing Body shares our view may be inferred from the terms in which it has prescribed the powers, duties, and status of the holder of this key position. It is an office calling for unusual qualities of mind and temper, and a wide experience in diverse fields of practice, teaching, and administration. The opportunity is here if the right man can be found.

EPSOM COLLEGE

It is customary at this season to commend to the notice of our profession the work of the Royal Medical Foundation of Epsom College, and this year in particular the appeal is deserving of sympathetic attention. As mentioned in the *British Medical Journal* of July 4th (p. 29), the governors of the College resolved at a special meeting last June to take, as soon as possible, the necessary parliamentary action to allow pensions to be provided by the Foundation for medical women and to render their sons eligible for election as Foundation scholars on the same conditions as those applicable to medical men and their sons. This extension of the benefits of the Foundation will remove a real grievance, for there is no justification for excluding medical women and their sons from the benefits of medical charities now that women have been admitted to the profession on equal terms with men. At the same meeting it was decided to abolish the present method of electing pensioners, annuitants, and Foundation scholars, and to substitute a system of electing these beneficiaries by a committee composed of ten members of the court

the College and ten other governors. This will prove less costly in administration, and remove any undue emphasis which a system of voting by ballot gives to the benevolent element of the school. It should be a boon to candidates seeking election, since they will no longer have to canvass for votes, which involves an expenditure they can ill afford. The new method of election will also assure preferential treatment for those whose need is greatest. One result of the present economic crisis must, we fear, be an increase in the number and the urgency of applications for the benefits provided by the Royal Medical Foundation of Epsom College. It will be impossible to meet this demand in any degree unless more and larger contributions are forthcoming. In view of the great help which has been given by the Foundation to less fortunate members of the medical profession for many years past, it is earnestly to be hoped that new subscribers will come forward at this special time of need, and that those who have hitherto supported the charity will endeavour to increase their subscriptions. The council of Epsom College has recently reviewed the expenditure on the management of the school, and is effecting economies in administration. In the advertisement which appears in our present issue details will be found of the new school sanatorium opened by Lord Dawson last October, together with particulars of the benefits provided by the Foundation.

TREATMENT OF SCHISTOSOMIASIS

Endemic haematuria had been known since prehistoric times in Egypt when in 1851 Bilharz discovered the causal parasite and showed that the pathological changes were due to the worm and its ova. Leiper in 1914 elucidated the complicated life-cycle, and pointed the way to rational prophylactic measures ; but it was not until about the same time that a rational specific treatment was employed against this parasite and the other closely related species which Leiper proved caused the bilharzian dysentery. Until then various drugs—malefern, salvarsan, quinine, and so on—had been employed with varying degrees of failure. In 1913 Tsamis, in Japan, employed emetine successfully against the Far Eastern parasite, and it was quickly employed in Egypt with encouraging results. It proved quite effective, but not entirely free from danger. In 1918 Christopherson and McDonagh advocated the use of potassium antimony tartrate, and, while this gave good results, it also was not entirely free from danger, even in experienced hands. Both drugs had the practical disadvantage that a considerable amount of time was necessary for complete cure. In no country is the treatment of bilharzia disease more important than in Egypt, where about ten of its fifteen million inhabitants suffer from the infection. In an attempt at amelioration, travelling and stationary hospitals dealing only with schistosomiasis and ankylostomiasis have been established, and up to 1928 over a million cases had passed through them. Dr. Khalil has recently published a comprehensive review of their work,[1] and analysed the effects of the now established therapeutic measures as well as the attempts to find a safer substitute for emetine and tartar emetic which would secure a cure in a reasonably short space of time. Various complex antimony compounds have been tried from time to time. Antimosan —a complex antimony salt of pyrochatechin—was, for example, tried with some success, but a certain proportion of patients could not tolerate it ; and in an attempt to overcome this disadvantage Schmidt was led to produce a sodium instead of a potassium salt, under the name of " fouadin." This drug has been tried out on a considerable number of patients, and proved to have several well-marked advantages over tartar emetic. The duration of the treatment is about ten days less (twenty instead of thirty) ; the therapeutic capacity of the unit is increased, and the same staff can therefore treat more cases ; and there is an absence of local complications after injections. Its disadvantages lie in the greater expense (tartar emetic is very cheap, and its preparation for injection is simple) ; it causes bradycardia in certain cases ; and its preparation is the monopoly of a single firm. These disadvantages do not seem to be insurmountable, and although more extensive use of the new drug is necessary before any definite opinion can be expressed, it would seem that in fouadin we may possess a drug which will be of great assistance in anti-bilharzial campaigns.

PNEUMONIA IN SOUTH AFRICA

The annual report for the year 1930 of the South African Institute for Medical Research contains an interesting review of certain ideas on the epidemiology of pneumonia, as it occurs among the native workers on the Witwatersrand gold-fields, derived from data which have been accumulating over a considerable period. There are indications that a change has occurred in the variety of pneumonia affecting the native population, the change taking the form of an influenzal modification, the pneumococcus being no longer the principal infecting agent. From the immunological aspect, too, the disease has obviously changed its character. During the years following the introduction of prophylactic inoculation of native mine labourers with a polyvalent pneumococcal vaccine there had resulted a marked diminution in the incidence of pneumonia. From about the year 1926, however, the vaccine has apparently been exerting a somewhat lessened influence in preventing the disease. In a native mining population of nearly a quarter of a million the mortality rate from lobar pneumonia, though it fell from 2.64 per 1,000 in 1923 to 2.52 in 1926, rose sharply to 3.48 in 1927, this figure being sustained in subsequent years, and reaching 3.60 in 1930. In a consideration of these figures it must be borne in mind that the vaccine used for the preventive inoculation against pneumonia was designed to protect against a pure pneumococcal infection. The recovery of organisms other than the pneumococcus, in the cases now occurring, suggested the use of a mixed vaccine. The procedure adopted is to investigate bacteriologically the flora in the individual mine concerned, and to prepare a " community autogenous vaccine " from the various micro-organisms common to the particular mining population. Another interesting point emerging from recent investigations is that there are two peaks of high pneumonia incidence during the year. Further, cases occurring in the winter tend to be associated more with the streptococcus-influenza group of organisms, while those of the summer more frequently have the pneumococcus alone as their infecting agent. The suggestion

has been made that pneumonia might be due to a primary infection by a filterable virus followed by a secondary pneumococcal invasion. A number of experiments to investigate this hypothesis have been carried out as opportunity occurred, but a whole series of inoculations have yielded entirely negative results. In order to determine whether malarial infection is in any way associated as a factor in the causation of pneumonia in native mine workers, a series of lung and splenic smears were made at post-mortem examinations. The results have, however, been negative. Another small experiment was carried out to test the infectiousness of the present variety of pneumonia for white mice. A number of these animals were kept for many months in different parts of a pneumonia ward in one of the native mine hospitals on the Rand, during a period when the beds were continuously occupied by persons with acute respiratory diseases. The mice were entirely unaffected, and were returned fat and obviously healthy.

DELAYED TERTIAN MALARIAL INFECTIONS

The annual curve showing the prevalence of simple tertian fevers in the temperate regions has two maxima: one in May and early June, the other in July and autumn. Dr. E. Martini[1] says that the earlier is due to infection from the previous year, delayed or latent primary cases, or to relapses, as was proved, he thinks, by German war observations in 1916; the second to acute infections, immediately following mosquito attacks. Why do the latent cases develop so early in the year? That he explains on the theory that there is for simple tertian a "flowering time" about May, due, according to the observations of Lenz and Reinhard, to the advance of summer weather and the stimulation of the malaria parasites by the strengthening of the sun's rays as it gets further north. The alternative explanation, by Colonel S. P. James and the Dutch school, that the malaria parasites themselves again become active seven to nine months after infection, inspires him with less confidence. The question whether a particular bout is a primary attack or a relapse is of little clinical importance, but has interest, and can be less uncertainly answered in non-malarial districts, as at Hamburg; that is why Dr. Martini calls attention to two cases that occurred there. In 1927 mosquitos infected with benign tertian malaria were received at Hamburg for treating general paralysis, but only a few cases were then coming forward, and the mosquitos were gradually dying off. In his absence, Dr. Martini's assistant, Fraulein Vollmer, let the last of them bite her on June 1st, 1927; she had no symptoms or signs at that time, though frequently examined; but nearly a year later, on May 29th, 1928 (she had had a fall from her horse on the 28th), with no intervening opportunity for infection, she had a rigor and pyrexia, and two further attacks on May 29th and June 2nd. Many gametes were found, proving that this was an old infection. She took plasmoquine, was at once cured, and had a rapid convalescence. Dr. Martini was himself infected in 1930, in the Pontine marshes, between July 21st and 27th. On August 6th and 8th he had what seemed to be slight attacks, but no evidence was found in his blood. He took a little quinine, and there were no further symptoms at this time, but nine and a half months after infection, on May 12th, 1931, he had slight chilliness, and on the next day tertian rings and gametes were seen in his blood; a typical attack followed on the 14th, which he cured with plasmoquine. He notes that though his first attack was abortive, his second was acute, and observes, as a possible explanation of its occurrence in May, that the weather had got warmer, with bright sunlight since May 3rd. Both these attacks, it will be noted, appeared in May. Dr. Martini refers to various observations on bodies of troops who moved in autumn from a malarial to a non-malarial district, where, alone of the people in their new area, they developed malarial attacks in the spring, proving they had brought their infection with them, though it had long remained latent. Accordingly, he gives the weight of his long experience to the theory of a "flowering time" for tertian in the spring, particularly in May and the first half of June, and thus he explains why delayed primary or latent cases occur about May, later than Colonel James and the Dutch school would expect.

PHARMACOLOGICAL MEMOIRS

In connexion with the twenty-fifth anniversary of the foundation of the National Pharmacological Institute in Rome its director, Professor Serono, has published a volume containing his scientific communications and memoirs,[1] representing forty years' work in the field of research. The memoirs, sixty-two in number, deal with a variety of pharmacological problems, among which those relating to the physiological action of the lipoids, the digestive ferments, and the therapeutic action of calcium and magnesium, are of more especial interest. Serono's best-known work is that relating to the preparation and therapeutic action of lecithin, the employment of which in human therapy he was the first to introduce (in 1897). Danilewski had already shown experimentally that injections of lecithin produced an increase in body weight and in the red cell count, but the employment of the agent in therapy was impossible with the lecithin as then prepared, owing to its rapid decomposition, with the formation of poisonous substances. Serono discovered that decomposition could be prevented by combining the lecithin with lutein, and he succeeded in preparing from egg-yolk a lutein-lecithin compound, which was stable and innocuous on injection into the human subject. He found that the drug produced a general improvement in all cases exhibiting lowered metabolism. The somewhat complicated method of preparing the agent apparently led to the introduction of synthetic glycero-phosphate, but this, according to Serono, differs from the biological product in optical and other properties, and is relatively inactive. Serono's researches formed but a small part of his activities; he was more interested in educational problems. He early recognized the existing defects in pharmacological education. It was usual for men possessed of a mere smattering of chemical and medical knowledge to undertake specialized laboratory work, and he conceived the ambition of founding a scientific laboratory in which co-workers should have a thorough knowledge of biology, chemistry, and physics, as well as of both physiology and clinical work—the former being [illegible]

[1] *Memorie e Comunicazioni Scientifiche (1897–1931) di Cesare Serono.* Roma: Istituto Nazionale Medico Serono. 1931.

for the preparation of remedies, the latter for their proper application. From small beginnings in two rooms he gradually built up the National Institute of Pharmacological Medicine in Rome, with its numerous staff; there his principles are embodied, and thence pharmacological preparations have been diffused into all parts of the world.

THE PROBLEM OF THE OUT-PATIENT

The Prince of Wales, at the last meeting of the General Council of King Edward's Hospital Fund, announced his intention, as president of the fund, of appointing a committee to inquire into the methods in use in the out-patient and casualty departments of London voluntary hospitals.[1] His Royal Highness has now constituted the committee, which is to be called the "Out-Patient Committee, 1932," with the following membership: The Earl of Onslow (Chairman), Sir John Rose Bradford, Bt., M.D., Lieut.-General Sir George Macdonogh, Dame Helen Gwynne-Vaughan, Mr. E. W. Morris, Mr. Isidore Salmon, M.P., Dr. F. E. Fremantle, M.P., and Mr. R. H. P. Orde. The terms of reference and powers of the committee, as defined by the General Council, are: "To inquire into and report upon the methods in use in the London voluntary hospitals regarding the attendance of patients in the out-patient and casualty departments, and the effect of those methods upon the suitability of the patients treated, and on the length of time during which patients wait before or after treatment; and to make such recommendations thereon as may seem to them desirable." The committee has discretion to present a single report on the whole question, or interim reports on separate parts of the question, and, in particular, on that part which is concerned with the internal arrangements or administration of the departments, as affecting the time of waiting. A report has been prepared by the Committee of Management explaining the origin of the inquiry. Communications should be addressed to Mr. H. R. Maynard, King Edward's Hospital Fund for London, G.P.O. Box 465A, 7, Walbrook, E.C.4.

RICHARD LOWER

Richard Lower, the tercentenary of whose birth falls this year, was a native of St. Tudy in Cornwall. He was educated at Westminster School and at Christ Church, Oxford. In February, 1665, he performed the first blood transfusion from one animal to another, and suggested its possible application to human beings. This was successfully realized by Denys of Paris in June, 1667. Lower's greatest work is the *Tractatus de Corde*, published in London in 1669. Here he fully describes the anatomy of the heart. He observes that it continues to beat long after its removal from the body; he measures the output of the ventricles, and compares the colour of the blood on entering and leaving the lungs, attributing the change to absorption of air in the latter. Later he practised in London, and he attended Charles II in his last illness. He died in comparatively poor circumstances in 1691. Lower possessed the true scientific spirit, an enduring love of truth, and a genius for experimentation. His style was terse and vivid. We understand that a forthcoming number of the *Proceedings* of the Royal Society of Medicine will contain a paper by Dr. K. J. Franklin, on "The work of Richard Lower: a tercentenary survey," read in title at a meeting of the History of Medicine Section on December 2nd.

[1] *British Medical Journal*, December 19th, 1931, p. 1149.

The King, on the recommendation of the Minister of Health, has approved the appointment of Dr. William Rees Thomas as a Medical Senior Commissioner of the Board of Control, in succession to Dr. Arthur Rotherham. Dr. Rees Thomas has been medical superintendent of the Rampton State Institution for Mental Defectives since 1920.

MEDICAL CONGRESSES, 1932

The following congresses and conferences on medical and allied subjects have been announced for 1932. Particulars are given below in the following order: date, name of organizing body, place of meeting, name of person to whom inquiries should be addressed. More detailed information about these meetings is given from time to time, as it becomes available, in the news columns of the *British Medical Journal*.

February.—German Association for Occupational Hygiene. Nuremburg. Secretary of Association, Platz der Republik 49, Frankfort-on-Main.

March 15–16.—International Society of Surgery. Madrid. Dr. L. Mayer, 72, Rue de la Loi, Brussels.

April 11–14.—German Society for Internal Medicine. Wiesbaden.

April.—German Society for Urology. Vienna.

May 9–13.—American Medical Association. New Orleans. Secretary of Association, 535, North Dearborn Street, Chicago.

May 10–15.—Royal Institute of Public Health. Belfast. Secretary of Institute, 37, Russell Square, W.C.1.

May.—International Union of Local Authorities. England. Mr. G. M. Harris, Ministry of Health, Whitehall, S.W.1.

June.—British Hospitals Association. Liverpool. Secretary of Association, 12, Grosvenor Crescent, S.W.1.

July 9–16.—Royal Sanitary Institute. Brighton. Secretary of Institute, 90, Buckingham Palace Road, S.W.1.

July 26–30.—British Medical Association Centenary Meeting. London. Medical Secretary, B.M.A. House, Tavistock Square, W.C.1.

July.—Congress on Paediatrics. Geneva. Secretary of Save the Children International Union, Geneva.

August 15–18.—International Congress on Light. Copenhagen. Dr. Kissmeyer, Finsens Lysinstitut, Strandboulevarden, Copenhagen.

September 6–9.—International Union against Tuberculosis. The Hague. Secretary of Union, 2, Avenue Velasquez, Paris VIII.

September 12–17.—International Congress of Tropical Medicine. Amsterdam. Professor E. P. Snijders, Institute of Tropical Medicine, Mauritskade 57, Amsterdam.

September 20–25.—International Congress of Maritime and Hygiene. Marseilles. Dr. Violle, 40, Allées Leon Gambetta, Marseilles, or Dr. Broquet, 195, Boulevard St. Germain, Paris VII.

October.—French Congress of Stomatology. Paris.

1932.—International Congress of Oto-rhino-laryngology. Madrid.

1932.—Italian Congress of Urology. Bari.

1932.—Pedagogic Medical Congress. Rome.

1932.—German Dermatological Society. Vienna.

1932.—Society for the Study of Diseases of Digestion and Metabolism. Vienna. Professor von den Velden, Bambergerstrasse 49, Berlin, W.30.

1932.—International Conference on Tuberculosis. Davos. Secretary, Medical Society, Davos-Platz, Switzerland.

BRITISH POST-GRADUATE HOSPITAL AND MEDICAL SCHOOL

STATEMENT OF PROGRESS

As recorded in our last issue at page 1149 the Governing Body of the British Post-Graduate Medical School is now prepared to receive applications for the important post of dean of the school. This announcement makes it opportune to review the progress of the scheme for the establishment of a British Post-Graduate Hospital and Medical School as a whole, and we print below the substance of a statement issued for publication on December 19th.

It will be remembered that the lines on which it was proposed to proceed were first explained in the House of Commons on April 9th, 1930, by Mr. Arthur Greenwood, the Minister of Health, in reply to a question by his predecessor in office, Mr. Neville Chamberlain.[1] The position then was that the Government had accepted the recommendations affecting the organization of a hospital and school devoted solely to post-graduate medical education made by a committee widely representative of the medical profession, of which Mr. Chamberlain and Mr. Greenwood had successively been chairman. This organization consisted of an existing public hospital—the Hammersmith Hospital, with 400 beds in modern wards, which, on its transfer from the local guardians in the spring of 1930, became part of the hospital service of the London County Council under the Local Government Act, 1929—and a new medical school to be built in conjunction with the hospital.

HOSPITAL, SCHOOL, AND HOSTEL

On the information then available the committee had contemplated that, apart from any expenditure on the hospital preparatory to its association with a post-graduate school, and from the cost of maintaining the hospital, both of which would be defrayed by the London County Council, the capital cost of building and equipping the school might reach £250,000; and that as no endowment for the school was in sight it must be contemplated that a further sum would be needed for its proper maintenance as a recognized school of the University of London.

Mr. Greenwood was able to announce that the Government was so much impressed with the importance of securing without avoidable delay the advantages of a proper system of post-graduate medical education in London, not only from the domestic, but also from the imperial and from the international point of view, that it would be prepared to contribute from public funds a maximum sum of £250,000 for building and equipping the medical school as an integral part of the scheme recommended by the committee, and to make provision for grants through the University of London towards the maintenance of the school on the lines already applied to comparable institutions of university rank.

A third element in the complete scheme outlined by the committee, in addition to the hospital and school, had been a residential hostel for students of the school, to be provided on a site in central London. For the accomplishment of this part of the scheme the Government relied upon private benevolence. An appeal was about to be made to the public for assistance in the establishment in London of a residential institution, to be called "London House," for use by students from the Dominions, not only in medicine, but in other arts and sciences. It was also proposed that London House should offer accommodation to a limited number of British students domiciled in Great Britain and Northern Ireland, in order to furnish collegiate association between them and students from the Dominions. Since then the voluntary efforts of those interested have already brought London House into being. Four houses in Bloomsbury were converted and furnished to accommodate thirty men students, and became ready for occupation in October.[2]

As regards the hospital and medical school, the position at the moment when a financial crisis developed last summer was that a provisional organization committee, under the chairmanship of Lord Chelmsford, had been appointed in the previous year to consider and report, in pursuance of the statement made by the Minister on April 9th, upon (1) the action requisite to lead up to the planning and construction of the medical school, and (2) the form of government appropriate to the hospital and medical school, and that on the basis of recommendations made by that committee a Royal Charter had been granted to the school in July.

GOVERNING BODY OF THE SCHOOL

The Charter entrusts the supervision of the building and equipment of the school, and its future management, to a Governing Body, at present consisting of the following members, nominated by the authorities shown below:

Lord Chelmsford (Chairman) ...	Minister of Health
Sir George Newman	
Dr. Barrie Lambert	
Mr. Silkin	London County Council
Mr. H. L. Eason	
Professor G. E. Gask	University of London
Mr. F. C. Goodenough... ...	
Lieut.-Colonel H. R. Dutton, I.M.S. (ret.)	Dominions Office India Office
Dr. A. T. Stanton	Colonial Office
Lord Dawson of Penn	Royal College of Physicians
Lord Moynihan	Royal College of Surgeons
Dr. Cecil Wall	Society of Apothecaries
Dr. T. Watts Eden	Royal Society of Medicine
Sir Robert Bolam	British Medical Association

Dr. Louisa Martindale and Dr. F. N. Kay Menzies have also been appointed members of the Governing Body under a power of co-option vested in the Governors by the Charter.

SUPPORT FROM PUBLIC FUNDS

It was inevitable that in the new financial situation not only the amount of money to be devoted to the scheme, but the question whether the country could afford the scheme at all, should be reviewed with great care; and it is gratifying to learn that the Government has been so anxious to avoid the indefinite postponement of the scheme that it has felt justified in deciding, notwithstanding the alteration in the state of public affairs since the financial basis of the scheme was first considered, to continue the policy of contributing from public funds for the building and equipment of the school. The maximum of the grant which Parliament will be invited to vote for this purpose will, however, in view of the exigencies of the time, be £100,000 instead of the maximum of £250,000 previously contemplated.

Since the scheme is founded upon the association of the medical school with a public hospital administered by the London County Council, the co-operation of the Council was essential to its continuance. It is therefore equally gratifying to learn that the Council's interest in the scheme is so great that, at a moment when it is called upon in the national interest to curtail expenditure out of the rates on many other projects in themselves desirable, it proposes to assist in bringing the scheme into practical operation by expending a capital sum equivalent to the Exchequer grant for the building and equipment of the school—that is, not exceeding £100,000—on developments and adaptations of the Hammersmith Hospital as are found to be most desirable at the

[1] *British Medical Journal*, April 19th, 1930, p. 745.

[2] Particulars of the terms for residence can be obtained on application to the Controller, Commander P. D. Crofts, R.N., London House, Caroline Place, Guilford Street, W.C.1

present time in view of its forthcoming association with the school.

It is not yet possible to say when the doors of the British Post-Graduate Hospital and Medical School will be opened to students, but the decisions of the Government and of the London County Council to treat the establishment of a post-graduate institution as an indispensable health service, and of the Governing Body of the school to appoint a dean forthwith, are welcome indications that a project which has for so many years been under discussion is now about to be realized.

THE ELECTROCARDIOGRAPH AND ALTERNATING CURRENT INTERFERENCE

BY

N. G. LETHLEAN

TEST ROOM SUPERINTENDENT, ELECTRICITY SUPPLY DEPARTMENT, DUNDEE

AND

W. S. MALCOLM, M.D.

ELECTROCARDIOGRAPHER, DUNDEE ROYAL INFIRMARY

After the corporation supply at the Dundee Royal Infirmary had been changed to alternating current, the cardiograms showed a definite superimposed ripple, with a frequency of 50 cycles per second; but the source of the interference was not readily determinable. The wards from which the patients were connected through to the cardiograph room had been wired many years ago for a direct current system of supply, and it was found impossible to trace the run of the wires and their conduits; or to discover whether the conduits were earthed and electrically continuous throughout the building. It was therefore decided that to remove the effect, rather than the cause, would be the most practicable method, particularly as the use of electrical appliances in the wards might set up a fresh source for the extremely small extraneous currents that had been disturbing the cardiograph circuit.

The interference could not have been caused by electromagnetic induction, as it persisted when all lights were

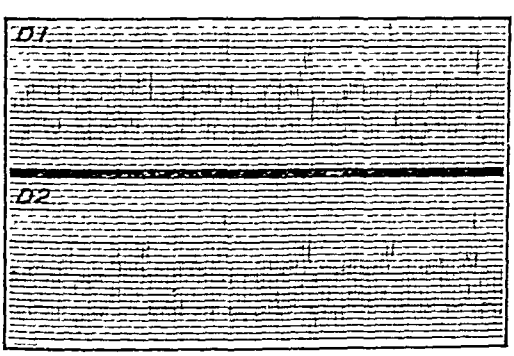

FIG. 1.

switched off. Electrical leakage was likely to have been negligible, as the resistance of the cardiograph circuit, including the rubber-covered flexible "patient leads" and the bed, was not under 10 megohms. The remaining source of interference was electrostatic induction, and currents due to this cause could flow if there was a difference of potential between the cardiograph circuit and the alternating current supply in near conductors. This condition was aggravated by the different capacities of the patient's body to the conductors inducing the currents. The point of lower potential was formed by the earthed metal conduit containing the wires running from the wards to the cardiograph room.

All traces of interference were successfully removed by using insulated flexible "patient leads" having a shrouding of braided wire, which was connected at the plug end to the earthed conduit, and at the "patient end" to the wire mattress of the bed. This placed the bed and the shrouding at earth potential, and formed a path of

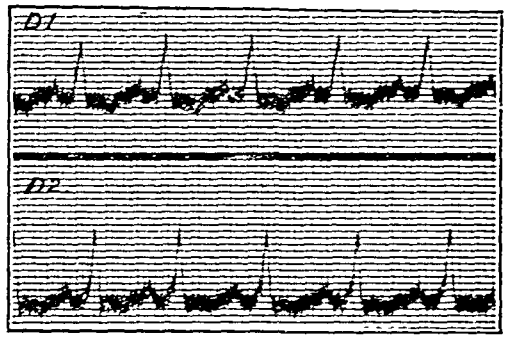

FIG. 2

low impedance for the capacity currents, which were consequently eliminated from the cardiograph circuit.

The ill-defined electrocardiogram (Fig. 1) shows the blurring effect of alternating current interference on the work of an electrocardiograph run on constant current. While the electrocardiogram was being taken the shadow of the moving fibre could be seen to lack definition and to have the appearance of being split into two, and in the finished electrocardiogram the two cycles can be made out in each twenty-fifth of a second in the time record.

Fig. 2 shows how complete has been the elimination of the interference, the two tracings being from the same patient, with a short interval, in order to emphasize the change which the cure had effected. Since the new leads have been in use there has not been the slightest recurrence of the trouble, and no other alterations have been made.

Ireland

Northern Ireland: Vital Statistics

The Registrar-General for Northern Ireland has now published his annual report for 1930. The number of marriages registered was 7,547, which gives a rate of 6.07 per 1,000 of the population. This rate is a slight increase on that for the previous year, and maintains the upward tendency in the marriage rate which began in 1927. There were 25,879 births registered during the year. The birth rate was 20.8 per 1,000, which is a slight increase on the rate for 1929, but 1.8 below the average for the ten preceding years. The death rate fell to 13.8 per 1,000, which is the lowest yet recorded for Northern Ireland. This rate is 2.1 below that for the previous year, and is 1.6 below the average for the ten preceding years. The death rate from tuberculosis continues to decrease, the rate for the year under review being 1.28 per 1,000, the lowest yet recorded. The deaths from this cause, however, still account for more than 50 per cent. of the deaths between the ages of 15 and 25, and 40 per cent. of those between the ages of 25 and 35. There was a further increase in the cancer death rate; 1,477 deaths from this disease were registered, giving a rate of 1.19 per 1,000, which is the highest yet recorded for Northern Ireland. The deaths of infants under 1 year of age numbered 1,754, or 68 per 1,000 births registered,

as compared with 86 in 1929. The corresponding infant mortality rates for England and Wales, Scotland, and the Irish Free State were 60, 83, and 68 respectively. Deaths registered as uncertified, owing to the fact that no medical attendant was present during the last illness, numbered 1,487 in 1930. This number is considerably smaller than that for the previous year, but it still represents 8.7 per cent. of the total deaths. The report (price 2s. 6d.) may be obtained from H.M. Stationery Office, 15, Donegall Square West, Belfast, or through any bookseller.

Cork Mental Hospital

An application was made recently to Mr. Justice Hanna, on behalf of the Minister for Local Government and Public Health, for a conditional order of mandamus to compel the Joint Committee of Management of the Cork District Mental Hospital to appoint as resident medical superintendent Dr. Bernard Francis Honan, Ennis, the person who had been recommended to them, pursuant to Section 6 of the Local Authorities (Officers and Authorities) Act, 1926. Counsel said that on November 6th, 1930, Dr. McCarthy, the resident medical superintendent of the Cork Mental Hospital, died, and notice of motion was given for a meeting of the Joint Committee to appoint Dr. Cashman, the senior assistant medical officer in the institution. On December 22nd the Local Government Department wrote refusing to sanction the appointment of Dr. Cashman. Resolutions and requests passed between the Joint Committee and the Minister, and on April 2nd of this year the Department requested the Local Appointments Commissioners to recommend a suitable person to fill the position. A recommendation to appoint Dr. Honan was accordingly made, on August 13th, to the Joint Committee, and after correspondence with the Local Government Department the Joint Committee, on October 20th, adjourned consideration of the whole question, and stated that it was about to seek legal advice regarding its position. Mr. Justice Hanna granted the application.

Insurance Fund Valuation

A report read at a recent meeting of the approved societies stated that the proportion of insured persons entitled to additional cash and medical treatment benefits had been reduced from 77 to 34 per cent. following the third valuation of approved societies, and that women, while paying a lower weekly contribution, drew more heavily on the funds than men. The third valuation of assets and liabilities of societies taken as at December 31st, 1928, showed that national health insurance in the Irish Free State had entered upon a new phase as a result of the issue of the Government actuary's report. The additional benefit schemes consequent upon the second valuation had automatically expired on July 5th, since then the new schemes approved by the National Health Insurance Commission had been brought into operation by societies which had a certified "disposable surplus." While the actuary had disclosed the financial position of each society individually, he had not yet made his report on the operations of the societies as a whole during the period of five years comprehended in the valuation, and, until it came to hand, no clear view of the trend of national health insurance finance could be obtained. It was possible, however, from a summary of the results supplied by the Insurance Commission, to submit some figures which, when contrasted with those of the second valuation, indicated—as the societies feared when discussing the question last year—that a distinct falling-off had taken place in regard to the surplus available for extra benefits. The third valuation covered sixty-five approved societies, one being a society of nineteen branches separately valued. This number showed a reduction of fifteen societies within a period of five years—a matter of some concern to those engaged in the administration of national health insurance. The total number of insured persons was 408,812 (284,299 men and 124,513 women)—virtually the same as in 1923. In respect of fifty-five societies, assets exceeded liabilities by £513,626, and of this sum the valuers certified £237,376 as disposable by one or more of the scheduled additional benefits, and the balance of £276,250 to be carried forward to the next valuation. It was found that ten societies had deficiencies totalling £51,268, which would be made good, so far as possible, out of their respective contingency funds. Another feature of the situation was that the reduction in the standard of extra benefits, which necessarily followed the unfavourable valuation, did not affect insured persons equally. Certain localized societies, mainly the smaller ones, had substantially improved their financial position as the result of a high contribution income, low sickness and disablement experience, or other causes, with the result that surpluses were concentrated on a smaller number of persons than before. It would appear that the larger societies, operating over wide areas, and particularly in the rural districts, had suffered heavily, both from the small number of contributions and from high benefit costs. The disproportionate strain on insurance funds arising from payments to women members continued to be a very disturbing feature of the valuation, and is one for which a remedy must be sought.

England and Wales

Tuberculosis in Lancashire

The annual reports of the central tuberculosis officer of the Lancashire County Council are always interesting, for each year Dr. Lissant Cox chooses special topics for consideration, thereby indicating the progress that is being made, first in one direction and then in another. In the report for 1930 he gives details of the investigation conducted at the Ashton-under-Lyne chief dispensary by Dr. G. Fletcher on the effects of dust in the cardrooms of cotton mills upon the respiratory organs of the workers in them. Dr. Fletcher states that the result of this investigation seemed to show: (1) that employment in the cardroom is attended by an excessive degree of respiratory disability, the main symptoms being cough, sputum, and dyspnoea; (2) that these symptoms are only established after years of exposure, and that the final condition of the chest is one of bronchitis and emphysema, with asthma as a complication in a few cases; (3) that the chest condition does not differ essentially from that accompanying chronic bronchial catarrh in an industrial area, but that in the case of the cardroom worker the symptoms have a weekly cycle, being usually most pronounced on Monday, and diminishing on subsequent days; and (4) that the *x*-ray findings vary only in degree from those of chronic bronchial catarrh, the lung markings and root shadows being in many cases, but not in all, more definitely and constantly enhanced than would be expected in cases of pure chronic bronchial catarrh. Elsewhere in the report there is a summary of the after-histories of children who came on the county dispensary registers during the six years 1922–24 and 1925–27, for the treatment of pulmonary tuberculosis. Of 273 children under the age of 15, with negative or absent sputum, who first received treatment in 1922–24, 75 per cent. were fit and well at the end of 1930. Similarly, of 311 children first receiving treatment in 1925–27, 73 per cent. had progressed to recovery, arrest of the disease, or quiescence. Examination of the records of children with positive sputums brought to light similar unfavourable after-results in these cases, however, and emphasized the urgent need for treating the disease before tubercle bacilli appear in the sputum. Before the ad-

of 12 it is comparatively rare for bacilli to be found, and most of the positive sputum cases in children occurred between the ages of 12 and 15, and then particularly among girls. Tubercle bacilli are discoverable in children either at the beginning of treatment or within twelve months in 82 per cent. of cases, and treatment of older children and young adults with positive sputum has so far produced much less satisfactory results than is the case in corresponding groups of patients at other ages. Greater attention is now being paid to dealing with these patients by surgical methods, such as artificial pneumothorax and phrenic evulsion. This last procedure is most successful in the sanatorium type of patient; many of the pulmonary hospital type eventually require thoracoplasty.

The death rate in the county from pulmonary tuberculosis in 1930 was the lowest on record; since 1923 there has been a continuous decline, with the exception of one year. The death rate from non-pulmonary tuberculosis is also the lowest on record, the most remarkable diminution occurring in the first five years of life; in 1914 there were 286 deaths, and in 1930 only 70. The county death rate for tuberculosis is, and has always been, less than that for England and Wales as a whole. Commencing with two experimental light centres in 1925 the county scheme has been extended, and there are now twelve such centres at the county dispensaries. The results of treatment of cases of non-pulmonary tuberculosis in 1930 were again particularly satisfactory among the skin and adenitis groups of cases with abscess formation. Of the total patients attending the light centres, 79 per cent. were able to continue their normal occupation during the course of treatment. As the result of the conservative diagnosis of pulmonary tuberculosis in children, it has only been necessary to provide a few sanatorium beds for them in Lancashire, with consequent saving of public money. The rejection of 59 per cent. of children in the first fifteen years of life who had been referred for treatment as possibly tuberculous appears to have been fully justified; very few subsequently returned to the dispensary as definite cases. Of 1,414 young adults coming on the dispensary registers as new pulmonary cases, only 0.91 per cent. had been previously rejected in childhood by the tuberculosis officers; the corresponding figure for non-pulmonary cases was 0.78 per cent.

Red Cross Blood Transfusion Service

The Duke of York, as chairman of the Council of the British Red Cross Society, attended the society's headquarters, on December 16th, to present honorary life membership certificates and badges to Mr. and Mrs. P. L. Oliver for their work in organizing and supervising the Red Cross Blood Transfusion Service. Sir Arthur Stanley, chairman of the Executive Committee, said that it was on His Royal Highness's own motion that life membership was conferred on Mr. and Mrs. Oliver. The Red Cross Blood Transfusion Service, he recalled, began in 1921 as a result of a request for a blood donor from a local hospital, received by the Camberwell Division, of which Mr. Oliver was then honorary secretary. Mr. Oliver formed a circle of Red Cross members to meet the real need for a service of this kind. In 1924 the demand had increased so much that he had to appeal for outside volunteers. The London Blood Transfusion Service was then formed, with Mr. Oliver as honorary secretary, and in 1925 428 calls for donors were received and supplied. Until 1925 Mr. Oliver ran his work as divisional secretary as well as the Blood Transfusion Service, but by then the increase in calls for blood donors had become so great that he had to resign his divisional secretaryship and devote his whole time to the service, which now had over 1,300 donors on its books. In 1930 1,627 transfusions were carried out, as against 1,333 in 1929, and up to the beginning of this month 1,980 donors had been supplied. The rise in the figure last year and this, said Sir Arthur Stanley, was all the more significant when it was remembered that the success of liver treatment in pernicious anaemia had in many cases made successive blood transfusions unnecessary. Mr. Oliver's office was open day and night, and his telephone had only once been left unattended during the eleven years the service had been in existence; that was during five days in 1926, when a change of administration was taking place. On an average six calls a day were dealt with, but frequently ten or more were received. The record number was eighteen. "It is no small task," said Sir Arthur Stanley in conclusion, "to maintain a twenty-four-hour service year in and year out for so long a time, when holidays, illnesses, and accidents are taken into account." The Duke of York then handed the certificates and badges to Mr. and Mrs. Oliver.

Correspondence

CHLOROFORM IN LABOUR

SIR,—On page 1089, in the *Journal* of December 12th, Dr. Bethel Solomons is reported as having said: "As chloroform was killing women in most maternity hospitals, he had adopted ether at the Rotunda." If it is doing this in maternity hospitals, one would surely expect like results in ordinary midwifery practice outside. But is it so? I have always believed, and heard it preached by my teachers over forty years ago, that this anaesthetic was so safe in labour that a death was unknown, and that there was some unknown condition present during labour which made chloroform safe. Anyway, I can speak from my own experience. I have practised midwifery in a rural area for forty years, and I have given this anaesthetic, and no other, in hundreds of cases under all kinds of conditions, and for such operations as one can do single-handed (turning, forceps, etc.); I have never had an occasion that even gave me a moment's anxiety, and I have never seen a death nor anything near it; and, besides, I have not heard of any of my neighbours having had one.

I wonder if Dr. Solomons's case is that, whenever a woman dies during childbirth, and chloroform has been used, it was this anaesthetic that caused death, directly or indirectly. As I have never heard of a death from chloroform during labour, I hope someone else with a knowledge and experience of this important matter will take up the whole question, so that we general practitioners may know where we stand with regard to this amazing statement of Dr. Solomons, which requires some qualification.—I am, etc.,

Felton, Northumberland, Dec. 15th. ROBERT A. WELSH.

DEATHS ASSOCIATED WITH ANAESTHETICS

SIR,—The accuracy of the statistics quoted by Dr. Hoffman may be open to question, as indicated by your correspondents, but this possible inaccuracy should not divert our attention from the fact that deaths under anaesthetics are increasing in number in this country at an astonishing rate. Within the years 1922-29 this number has become more than doubled, while the American figures remain about constant for the same period. Errors of registration can hardly enter into such a consideration as this.

There is one outstanding difference between the methods adopted in America and in this country, which, in my opinion, largely accounts for the disparity. In America the use of chloroform has been almost entirely abandoned,

but in England its use is unrestricted, chiefly in the form of a mixture with ether.

In 1922[1] I pointed out how the records of deaths were tending to shift from those under pure chloroform to those under chloroform mixtures, owing to the increasing use of the latter, and in 1929 we find the mortality under the mixtures double of that under chloroform alone. This is not the whole story. In 1911 the number of deaths recorded under ether was 19, and in 1929 it was 263—that is, 36 per cent. of the total deaths. I have already, elsewhere,[2] expressed the opinion that the enormous apparent rise in the mortality of ether is illusory and due to faulty certification; that the ether has in fact, in most cases, been preceded by chloroform, or a mixture of chloroform, given as a convenience in the induction of anaesthesia. This is the only explanation I can offer of this otherwise inexplicable and apparent change in the toxic character of ether vapour.

Deaths under the three categories of "chloroform," "chloroform mixtures," and "ether" contributed 80 per cent. of the total in 1929, and it is therefore admissible to correlate the difference between the mortality incidence in America and in this country with the definite divergence in the methods adopted, at least, this should be the first line of inquiry—I am, etc.,

London, W 1, Dec 15th A. Goodman Levy.

SECONDARY HAEMORRHAGE AFTER SUPRAPUBIC PROSTATECTOMY

Sir,—When secondary haemorrhage occurs after this operation it is due to the separation of a slough opening a vessel, it is unavoidable, therefore, and liable to occur after the "open" (Thomson-Walker) as after the "closed" (Freyer) operation. If genito-urinary surgeons had their cases "grouped" before operation, and transfused before haemorrhage caused anxiety, "secondary haemorrhage after prostatectomy" (*British Medical Journal*, December 12th, p 1078) would cease to have any terrors, and painful local treatment, with packing or various modifications of de Ribes's bag, would be unnecessary—I am, etc,

London, W 1, Dec 15th Sydney G. MacDonald, F.R.C.S.

EPIDEMIOLOGICAL REPORTS OF THE LEAGUE OF NATIONS

Sir,—Referring to Dr Y. Biraud's letter in the *Journal* of December 12th, I am well aware that there must inevitably be some difference between the figures published monthly and those published yearly in official reports, owing to errors due to causes of which every person who has had to deal with statistical returns is aware; but I submit that the discrepancies in the typhus figures for the Federated Malay States, to which I drew attention, are too marked to be thus explained.

Dr Biraud writes that "typhus was not compulsorily notifiable at the date in question"—that is, 1927 to 1930. How, then, does he account for the statement made by the writer of the article on typhus in No. 133 (p. 493) of the Monthly Reports, which reads as follows: "The first cases of this disease were notified in the Federated Malay States in 1924, 11 cases . . ." and for the figures published in the reports for the first time in No. 119 (October, 1928), and continued ever since?

Dr Biraud writes further that "'tropical' typhus was only made compulsorily notifiable in the Federated Malay States in 1930". This statement is quite irrelevant to my argument, which was concerned with typhus as a whole, and not with any variety, or supposed variety of it. Curiously enough, however, typhus, according to the Monthly Reports, began to be "tropical" just about the time it began to be severe.

When I find serious discrepancies in respect of the notifications of one important disease in an official publication I become suspicious of those relating to other diseases.—I am, etc.,

West Hampstead, N.W., Dec. 15th. E. W. Goodall.

[1] *Chloroform Anaesthesia*, 1922
[2] *Lancet*, January 22nd 1927.

NERVOUS DYSPEPSIA

Sir,—The diagnosis of nervous dyspepsia, the subject that was discussed at the Royal Society of Medicine on November 24th, rests primarily on the failure to detect any organic cause for the symptoms. In the course of examining a number of these cases, using the opaque meal, I have found a large percentage have a definite degree of chronic duodenal ileus, and have been forced to the conclusion that this condition plays a very important part in the production of the group of symptoms which are clinically diagnosed as "nervous dyspepsia." In many of them the entire contents of a distended duodenum may be seen to regurgitate *en masse* into the stomach. This must surely cause considerable gastric disturbance.

This type of dyspepsia, which is very prevalent, not only distorts the patient's outlook on life, but the outlook of those with whom he comes in contact. A definite mental upset often accompanies this condition. In one case, where the patient showed a suicidal tendency, the presence of the characteristic atonic stomach, with an elongated and dilated second part of the duodenum, clearly indicated the end-results of a chronic duodenal ileus. A duodeno-jejunostomy led to complete recovery. The degree of severity varies, but it is the early stage of a chronic duodenal ileus that often escapes recognition by radiologists, and it is at this stage that much can be done to prevent the patient from becoming a "chronic abdomen."

Briefly, the earliest manifestations of a chronic duodenal ileus are the elongation of the second part of the duodenum, regurgitation of the entire contents into the stomach, and, finally, the dilatation of the duodenum itself. The causes may be congenital or acquired—I am, etc.,

London, W 1, Dec. 17th. S. Gilbert Scott.

THE CREOSOTE ENEMA IN PNEUMONIA

Sir,—I am interested in Dr. Ian Macdonald's letter in the *Journal* of December 12th on the creosote enema in pneumonia, because some years ago at the St. Marylebone Hospital I gave creosote to twenty-five cases of advanced pulmonary tuberculosis. In such cases systemic intoxication is often due to secondary pneumococcal or streptococcal infection. The dose, from 1 to 60 minims, three times a day, was given in capsules by the mouth. The wards and patients reeked of creosote, but the drug had no apparent influence on the disease. What did impress me was that 3 drachms of pure creosote a day did not corrode the viscera.

Yet on the published results the creosote enema merits an extended trial, and to prove the value of any treatment in pneumonia a large number of observations are needed. No disease is more fickle. I have seen crisis on the third day followed by recovery in a case where no special treatment was given—the laboratory attendant had misplaced an autogenous vaccine which I had intended giving on the second night. Had that injection been given I might have been writing now about vaccines in pneumonia.

If 20 minims of emulsified creosote per rectum were absorbed, the concentration of creosote in the blood would be approximately 1 in 6,000. On the Lister Walker scale cresol is three times stronger than [illegible]

It is also over ten times less soluble in water Nevertheless, it may be possible to determine *in vitro* whether serum with 1 in 2,000 phenol, or 1 in 6,000 cresol, is or is not lethal to the pneumococcus Having tried many disinfectants, *from iodoform to monsol*, by the intravenous route in advanced pulmonary tuberculosis, I doubt if any of them are likely to prove specifics for bacterial infections, because with all antiseptics the lowest concentration which kills bacteria *in vitro* would, if present in the blood, probably kill the patient The disadvantage of the intravenous method is the bulk of the injection, as the disinfectant must be diluted in normal saline to a point below the concentration at which it coagulates serum More over, the germicidal power of all disinfectants is greatly reduced *in the presence of serum*

It may be that the benefit of the enema and of the creosote in treatment and prophylaxis is indirect In so far as the large intestine is cleared and sterilized, the production and absorption of intestinal toxins would be prevented in pneumonia, and in any other disease — I am, etc ,

London, W S, Dec 14th HALLIDAY SUTHERLAND, M D

ASTHMA STATISTICS

SIR,—The Danish asthma statistics quoted by you in the *Journal* of December 5th are interesting in several particulars, but especially in connexion with the cutaneous tests for proteins Referring to these statistics, Mr Frank Coke, *in his letter to the Journal of December 12th, says*, 'Thus the skin reactions, which were at one time so much belittled, again receive confirmation" The confirmation they receive from the Danish statistics is that a positive reaction was obtained in 91 out of 188 cases, and *that in only 16 cases out of 150 could the patients* correlate the results of the cutaneous tests with their experiences and beliefs as to the causes of their attacks I suggest that almost as high a percentage could be made to show a positive cutaneous reaction among patients who are not asthmatics

It is a pity that H C Gram, in his Danish report, does not give the number of cases cured (by desensitization) among the 91 which gave a positive reaction This might have done something to answer Mr J E R McDonagh's statement in the *Practitioner* of July, 1929, that "hypersensitiveness means no more than augmented hydration, and removing the agent causing the same does not get rid of the factor which set the original hydration in motion It is for this reason that skin tests are valueless, based as they are on entirely wrong premisses"

After many years' experience of skin tests I have come to the conclusion that protein hypersensitiveness is merely a side issue in the study of asthma The value of skin tests is limited to their power of disclosing certain irritants which are capable of disturbing the stability of the vasomotor system and upon which depends the asthmatic condition —I am, etc ,

London, W 1, Dec 17th ALEXANDER FRANCIS

CHILD GUIDANCE CLINICS

SIR,—It is unfortunate that Dr H Crichton-Miller, before he wrote the letter published in your issue of December 12th, did not more carefully read mine appearing in the previous issue, on which he comments If he had done so he would have seen that nowhere therein had I made the proposal that "the work of child guidance should be relegated to the general practitioner" the last sentence in my letter states exactly the contrary

The method of conduct of these clinics criticized by me is that outlined in a letter in the *Journal* of November 28th, and it is not necessary to know anything about the intricacies of treatment, either physical or mental, in order to be in a position to form an opinion whether that method is good or bad Therefore Dr Crichton-Miller's conclusions in his last sentence become irrelevant We read in the letter of November 28th that the child is subjected, *unknown to the general practitioner who may be the lone doctor*, to "a psychiatrist, an educational psychologist, and a social worker," who alone, or with further assistance, provide "general and psychological medicine, educational psychology and teaching method, sociology, and economics" Dr Crichton Miller considers that to be "the essence of team work" When I venture to call it "mass treatment" he becomes annoyed What if at long last it were to be found that the key of all trouble was in someone else, and not in the child

Dr Crichton-Miller seemingly has no use for the general practitioner in his team, for he considers that, whilst receiving his patients direct from magistrates and teachers, it constitutes "the function of the social worker to visit the homes and to collect the family histories", and at the same time he advances as the excuse for this preference what one so often hears—that the "overworked" general practitioner is glad to be rid of this part of his practice, as he himself "is driven to mass treatment in coping with a large panel practice" The satisfaction expressed with the fact that magistrates, teachers—and shall we add clergy and social workers?—refer children direct to these clinics is a further instance of failure to realize what Sir George Newman constantly says in his reports—namely, *that the general medical practitioner is the foundation on* which any satisfactory medical service must be built. If this practitioner were consulted and given an opportunity to advise, warn, and guide the specialist with information which he (the only scientist entering the house of the child) has gathered from internal knowledge of the environment of circumstances and characters in that home, and if, at the same time, he were encouraged to keep active and further develop his knowledge of the simpler maladjustments of childhood, then there would be found in time to be few cases overlooked that required the intervention of magistrates, teachers, clergy, and other well-wishers of the child in order that something be done, whilst much misery and crime would be avoided The team required to deal with any form of mental or physical illness should be selected by the general practitioner, who alone is conversant with what is necessary and desirable, and to subject a child to the bombardment of mass treatment arranged for by the several specialist members of a self appointed and therefore imperfect team is not likely to produce the high percentages of satisfactory preventions and cures we are all out for

What does Dr Crichton-Miller consider to be the function of the general practitioner in medicine? There are at the present moment some 20,000 of them in the British Isles on whom during education over £30,000,000 has been spent. Naturally magistrates, teachers, clergy, and social workers prefer to have a report on the mental state of a juvenile delinquent from a specialist Are they to be considered to be competent to judge the position in medicine; and then, what now happens in places where no such specialists reside? This preference has been brought about primarily by the belittling of the general practitioner, and this not alone by members of the lay public Dr Crichton Miller may agree that if sufficient [illegible] drummed into the mind of a person that he is incompetent, foolish, and ignorant, *the result is that he becomes* more so Specialists fail to appreciate the latent force for good in the honest general practitioner I trust I did not lose sight of this then the whole of medicine and public health would gradually be lifted on to a far higher plane through cordial co-operation brought about between all grades in the medical profession

by the *Lancet* on a special commission to investigate the hygienic condition of Sicily. He was a member of the Aristotelian Society, and the author of valuable medical treatises, and of many contributions to the professional and philosophic journals. He also published a history of *The Lindsay Family in Ireland*.

For many years Professor Lindsay was a member of the British Medical Association, served on the Central Council in 1896-99, and held the office of president of the Ulster Branch in 1905. He was a joint secretary of the Section of Medicine when the Association held its Annual Meeting in Newcastle-upon-Tyne in 1893, and president of the same Section at the Annual Meeting in Belfast in 1909. For some years he acted as the Belfast correspondent of the *British Medical Journal*. On the occasion of his leaving Northern Ireland in 1928, to take up residence in London, he was entertained at a complimentary dinner by his colleagues on the visiting staffs of the Royal Victoria and the Belfast Maternity Hospitals.

Professor Lindsay was a bachelor ; his nephew, Captain D. C. Lindsay, is high sheriff of Belfast.

[The photograph reproduced is by Elliott and Fry, London.]

The medical life of East Durham has sustained a great loss by the death, on December 11th, of Dr. HUGH RUSSELL of Trimdon in his eighty-sixth year. He was a native of Airdrie, and passed his final examinations in medicine at Glasgow University with honours at the age of 20, but could not qualify until a year later in 1867. Six years later he proceeded to the M.D. degree. As a student he was a personal friend of Lister, and often assisted him in his experiments. In 1869 he settled at Trimdon, co. Durham, where for sixty years he held the appointment of medical officer to Sedgefield Rural District Council. Dr. Russell, who had come to be regarded as the father of the community as well as of the medical fraternity in the area, was a type of man now seldom seen, full of spontaneous courtesy and tenderness towards his patients and friends. To the younger generation of medical practitioners in particular his skill as a physician and his apt and generous counsel were an inspiration.

Dr. THOMAS CARTER, who died at Sutton Coldfield on November 21st, aged 90, was a native of Richmondshire. He was educated at Richmond Grammar School, and received his medical training at Guy's Hospital and in Paris. On qualifying M.R.C.S.Eng. and L.R.C.P.Lond. in 1863, he joined his uncle, Dr. Bowe, in practice at Richmond (Yorks). He practised there for forty-five years, and is still remembered with affection and esteem. In 1864 he contributed "Notes on some of the Paris hospitals" to the *Medical Times and Gazette*. He was a justice of the peace, and was for many years also on the militia medical staff (retiring with the rank of surgeon lieutenant-colonel) and medical officer to the Nineteenth Regimental District. Dr. Carter was a member of the British Medical Association until his retirement from practice twenty-three years ago, owing to increasing deafness. Within a few weeks of his death he was otherwise in full possession of all his faculties. He leaves four children, one of whom is a member of the medical profession.

The following well-known foreign medical men have recently died: Professor ALFRED MAYOR, formerly rector of Geneva University and president of the Geneva Medical Society, aged 78 ; Dr. HEINRICH ALBRECHT, a prominent Berlin hygienist and author of works on the hygiene of dwelling houses and occupations ; Dr. MAX ROTH, a Basle oto-rhino-laryngologist, aged 43 ; and Dr. PAULESCO, professor of medicine at Bucarest, and formerly the collaborator of the late Professor Lancereaux of Paris.

The Services

COMMISSIONS IN THE R.A.M.C.

Twenty-five permanent commissions in the Royal Army Medical Corps are being offered to qualified medical practitioners, under 28 years of age, registered under the Medical Acts. There will be no entrance examination, but candidates will be required to present themselves in London for interview and medical examination. At the same time, a certain number of temporary commissions under similar conditions as regards age and qualification will also be offered. Applications should reach the War Office not later than January 18th, 1932. All information as to conditions of service and emoluments may be obtained from the Under-Secretary of State, the War Office (A.M.D.1), Whitehall, S.W.1.

No. 14 STATIONARY HOSPITAL

The twelfth anniversary dinner of No. 14 Stationary Hospital was held in the Trocadero Restaurant on December 11th, with Colonel C. R. Evans, D.S.O., in the chair ; there was a good attendance. Proposing the toast of "The Hospital," Colonel Evans commented on the loyalty and comradeship which had been such a characteristic feature of the staff of this hospital during the war, and which was now still manifest in the regular attendance at the annual dinner. Colonel Perry, who responded to the toast, gave an account of the doings of members of the medical staff who had been unable to attend on that occasion. The remainder of the evening was spent in recalling old memories of the hospital's activities.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

National Health Insurance

Sir ARCHIBALD SINCLAIR, replying on December 10th to Mr. Rhys Davies, stated that certain minor amendments in the English Medical Benefit Regulations were proposed. The proposed Scottish Regulations would differ from the English Regulations in certain respects.

Replying to Mr. Rhys Davies on December 9th, Sir E. HILTON YOUNG said the Dental Benefit Regulations provided that a dentist should apply the same degree of skill and attention when giving treatment to an insured person as he would apply in giving treatment to a private patient. A dentist was not required, however, to enter into any general undertaking to provide treatment on the terms and conditions laid down in the Regulations to all insured persons who were entitled to dental benefit and who applied to him for treatment. Every such person was the subject of a separate contract, and the dentist was free either to accept or to decline the insured person as a patient under the conditions laid down in the Regulations. In the former event, he was expressly debarred from suggesting, demanding, or accepting any payment from the insured person beyond that provided by the prescribed scale, and the insured person was entitled to receive from his approved society the proper proportion of the cost of his treatment. In the latter event, it was not possible to prohibit the insured person from agreeing with the dentist to be treated as a private patient at such fees as might be mutually agreed between them, but in that case the insured person would not be entitled to claim any part of the cost of his treatment from his approved society.

In the year 1930 approved societies received State grants totalling £6,160,000. At the rate in force before 1928 it is calculated they would have received £8,470,000 in that year. For the year 1931 to September 30th the corresponding figures are £4,300,000 and £5,900,000.

Imported Milk and Butter

In reply to Mr. Glossop, on December 10th, Sir E. HILTON YOUNG said the Public Health (Imported Milk) Regulations did not impose any conditions as to *Bacillus coli* in imported milk, but the Regulations required that imported milk should conform to a strict bacteriological standard of purity which was not required in the case of milk produced in this country other than graded milks.

Replying to Sir Alfred Knox, on December 10th, he stated he was unaware that an outbreak of illness at Yeovil had been attributed to the consumption of butter but had received information of several cases of illness in a neighbouring district, in connexion with which samples of butter were examined, but found to be free from microbic contamination Russian butter, with other foods, was subject to examination at the ports, and there was no evidence to justify steps being taken to prevent its importation

Sir E. Hilton Young stated, in reply to the Duchess of Atholl on December 10th, that he did not think it necessary to lay down a standard of hygienic quality to which condensed and dried milk imported into this country must conform. Answering a suggestion by Dr Fremantle that consuls should be given power to report on the conditions under which such articles were prepared, he said that the law provided the Minister of Health with power to investigate the condition of such foodstuffs on arrival into this country That power was exercised.

Further answering the Duchess of Atholl Sir E Hilton Young said there was no prescribed standard of butter fat for skimmed milk, whether home produced or imported This article purported to be as nearly as possible free from butter-fat, and it would accordingly be impracticable to impose such a standard.

Notes in Brief

Answering Dr. Salter, on December 8th Sir Herbert Samuel stated that 601 pedestrians had been fatally injured by motor vehicles in England and Wales during the first nine months of 1931, as compared with 547 in the corresponding period of 1930.

Sir E. Hilton Young states that there are no regulations regarding the publication of annual reports by medical officers of health. Publication is a question for the decision of the local authority concerned

Medical News

The Royal College of Physicians of London will be closed from Thursday, December 24th, till Tuesday, December 29th, both days inclusive

The second half of session 1931–32 of the Medical Society of London opens on Monday, January 11th, with a pathological meeting On January 25th, at 8.30 p.m., a discussion on the causation and treatment of essential hypertension will be opened by Dr Geoffrey Evans and Dr G. Arbour Stephens A discussion on the syndrome of chronic toxic cholecystitis will be introduced on February 8th by Mr W. Harold Dodd and Dr Arthur Davies On February 22nd, Dr George H Oriel and Dr George W Gray will open a discussion on asthma and allied conditions On March 14th there will be a discussion on non-effective nephritis, introduced by Dr Arthur A Osman and Dr. Owen de Wesselow, and on March 21st Dr J F Brailsford will open a discussion on the diagnosis of diseases of the hip-joint The Lettsomian Lectures by Mr. F. A Williamson-Noble, on the reactions of the eye to general disease, will be delivered on February 29th and March 7th and 16th At the conversazione on May 9th Sir James Berry will deliver the annual oration, entitled "Fallen Idols" In view of economic conditions the annual dinner of the society will not be held in 1932.

A course of lectures on rheumatism and arthritis as a public health problem will be delivered at the Royal Institute of Public Health, 37, Russell Square, W.C The first of the series will be by Sir William Willcox, on the biology of rheumatism, with special reference to infective causes, on Wednesday, January 20th, 1932, at 4 p.m The lectures will be continued on subsequent Wednesdays at the same hour. The course will conclude on March 2nd at 11 a.m., when there will be a demonstration at the British Red Cross Society Centre for Rheumatic Diseases, 1 Eto Place, Regent's Park.

The next meeting of the Illuminating Engineering Society will be held at the house of the Royal Society of Arts (John Street, Adelphi, W.C.), on Friday, January 8th, when a discussion on "Motor car headlights" will be opened by Mr. E. S. Calvert at 7 p.m Copies of the introductory paper may be obtained from Mr J S Dow, 32, Victoria Street, S.W.

The ninth International Congress of the History of Medicine will be held at Bucarest, under the presidency of Dr. V. Gomoiu, in September, 1932 The exact date will be announced later. The principal subjects for discussion will be: (1) the evolution of medicine in the Balkan States; (2) the protection of Europe against bubonic plague. Excursions will be paid to Trieste, Athens, Constantza, and the neighbourhood of Bucarest.

Volume 2 of *The Veterinary Bulletin* will be issued monthly from January 1st, 1932, and will run to about 864 pages, including the index for each monthly issue and the final classified volume index It will cover the same ground as volume 1, but will be much more complete and will include references to all important British and foreign scientific work relating to veterinary research, administration, public health, and education Although it was originally intended that the issues for 1932 and onwards should cover only 600 pages annually, expansion has been necessary in order to deal with the amount of material available The subscription will be £2 for the volume, or 5s per copy, payable in advance, post free to any part of the world Communications should be addressed to the Imperial Bureau of Animal Health Veterinary Laboratory, Ministry of Agriculture and Fisheries, Weybridge, Surrey

The autumn issue of the Research Defence Society's quarterly journal, *The Fight Against Disease*, contains a warm acknowledgement of the services rendered by the late Lord Knutsford, who had been an energetic supporter of the society since its foundation in 1908, and was latterly its chairman An article on artificial respiration in the same issue discusses the progress that has been made in improving this procedure as the result of experimental work There is also a detailed discussion of the lawsuit arising out of the Grove-Grady will, under which the testator proposed to found an "animals' benevolent society out of her residuary estate It was finally decided by an order of the House of Lords, that no part of the sum of £25,000 to be retained by the trustees could be used for anti-vivisection propaganda Extracts from the judgement of the Court of Appeal are republished as being of particular interest to the Research Defence Society

On December 19th, Mrs Henry N Sporborg, acting on behalf of the Rugby Works Hospital Fund of the British Thomson-Houston Co., Ltd., laid the foundation stone of the Sun Pavilion Extension of the Hospital of St Cross, Rugby

Dr S Wigoder has been elected a member of the Morley Town Council and appointed to serve on the Maternity, Child Welfare, Health, and Waterworks Committees

The executive committee of the Food Education Society has placed on record its sorrow at the death of Sir Henry Baldwin, its vice-chairman for the last seven years

An oto-rhino-laryngological institute has been founded at Charkov in the Ukraine for the study, among other subjects, of the pathogenesis of diseases of the respiratory tract and deaf-mutism The institute contains a clinic, laboratory, library, museum, and out-patients' department

A society of surgery has recently been founded at Madrid, under the presidency of Dr Goyanes

Professor E Tanzi, director of the clinic of nervous and mental diseases at Florence, has retired on reaching the age limit, and has been succeeded by his former pupil, Professor M Zalla of Messina

The Rumanian journal *Spitalul* (The Hospital) has recently celebrated the fiftieth year of its foundation

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are *MUSEUM* 9861, 9862, 9863, and 9864 (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:
EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Mediseora Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS

Still's Disease

Dr. WILLIAM BELL (Bradford) writes: May I ask, through your correspondence columns, for information as to the measure of success which is obtained, or which fairly may be expected, in the treatment of Still's disease. One is aware of the gloomy prognosis held at the time Dr. Still published his account of the condition. Such progress may have been made since that success may be commonplace and not worth recording. Even to-day, however, the variety of treatment suggested, some of it drastic—for instance, malaria therapy—points to doubt about the issue. The doubt is perhaps justifiable, considering the nature of the condition. I have recently observed a typical case, in which there was restoration of apparently perfect health. From my very limited experience of the condition I wonder if this is usual.

Income Tax

Year Overlooked—Free Quarters

"J. S. R." received a hospital appointment in April, 1929, at £300, and later at £350, per annum. Quarters are provided, but he has to pay for meals, laundry, etc. He paid tax for 1930–31, and has since received a notice of assessment for 1929–30, and wishes to know whether it is correct that he should be assessed for the quarters which he was compelled to occupy.

*** Assessments can be made within six years of the end of the year to which they relate, so the assessment for 1929–30 is well within the time limit. As regards the quarters—if the terms of appointment provide for a monetary salary, subject to deduction for quarters, food, etc., then the amount of the salary is assessable even though the whole of it is not received in cash. On the other hand, if the "quarters" represent an additional benefit (or obligation) over and above the monetary remuneration fixed by the terms of employment, he cannot be assessed on the salary plus the value of the quarters, as he has presumably no right of letting, and cannot, therefore, convert the right of occupancy into money or money's worth.

LETTERS, NOTES, ETC.

Ventilation of Cinemas

Dr. T. GRAHAM-SCOTT (London, W.) writes: May I draw the attention of the medical profession, especially medical officers of health, to the insanitary condition of some cinema theatres. On entering them from the fresh air, the atmosphere is so foul that one can hardly breathe. Managers should be compelled to have better ventilation and not crowd the people so closely as they do, and at the end of a performance all doors and windows ought to be thrown open. The hygienic conditions of the older and smaller places are dreadful. They are a hotbed for germs of every kind, a source of infection from influenza and catarrh, and a general danger, because people are heated up for hours and then go out into the cold with nausea and headache from the unclean atmosphere. I do not say these conditions apply to the large and modern buildings, but certainly some of the others should be put down or modified.

Smoke Abatement and Income Tax

While no outstanding event is recorded in the second annual report of the National Smoke Abatement Society ended June 30th, it is evident that a great deal of constructive and pioneer work is being done by the society, not only in exposing the consequences of uncontrolled emission of smoke, but in directing attention to the most effective measures for its elimination. Thus, in the autumn issue of the journal of the society there are authoritative articles on smokeless fuel and on the progress of the electrical grid, in addition to notes on the public health aspects of smoke abatement as observed in various parts of the country. During the year under review several questions were asked in the House of Commons concerning legislation on the subject, and in the House of Lords a debate took place in which the suggestion was made that there might be a slight remission of rent in State-aided houses where there are no open fires, or a remission of income tax under Schedule A. The society estimates that if smoke could be abolished from this country in a single year, the benefit to the nation would be equivalent to a reduction of one-third of income tax.

Diet and Dental Caries

Dr. J. GORDON CAMERON (Kuala Lumpur) writes: The *Journal* takes three weeks to reach Malaya, and therefore, no doubt the correspondence on diet and dental caries will have come to an end some weeks before this letter reaches you. I write with the *Journal* of October 17th, containing Mr. F. W. Broderick's letter, in front of me. I have been most interested in Mrs. Mellanby's findings on diet in relation to dental caries, and have put them into practice whole-heartedly in my maternity work. Maternity patients here consult me early in pregnancy, and I invariably explain to them the importance of ample vitamins in their diet in relation to their own well-being and the well-being of the child to be. I ask them to take daily doses of a vitamin food prepared by a famous British firm, in which food are present vitamins A, B, and D, the last-named being in the form of irradiated ergosterol. I further ask them to take a small dose of calcium daily, plenty of fresh fruit, and give a few hints about exercise, bowel regulation, and the like. This routine I ask them to carry out from the time at which they first consult me up to the birth of the baby and for several months afterwards. As a result I find that dental caries almost invariably, does not occur during or after pregnancy; that at the end of pregnancy they are often healthier than before they became pregnant; that they are, as a rule, able to feed their babies themselves, and that the babies do exceedingly well, both in bone and tooth formation and in general health. As a mere general practitioner, the above practical findings are proof enough for me that Mrs. Mellanby has struck the nail on the head.

Treatment of Cataract

Dr. F. W. CORY (Leeds) writes to record that he has obtained good results in treating cataract with inunction of equal parts of ung. hydrarg. ox. flav. and white vaseline. A small quantity of the ointment is placed inside the lower lids; the lids are closed, and the eyes gently massaged for two or three minutes nightly. The following morning, after rising, the face is bathed with warm water, then directly afterwards sponged with cold water, and dried. Every focal sepsis should be carefully attended to. Diet and general measures for establishing a healthy state of mind and body must be taken into consideration. As an ophthalmic surgeon of over twenty-five years' experience in ophthalmology (he says), I affirm that cataract can be often cured, especially if treated sufficiently early.

Tetra Forceps

With reference to Dr. E. W. Lewis's improved tetra forceps (or towel clip), an account of which was given by him in last week's issue (p. 1142), the instrument in question is the uppermost of the four illustrated.

Vacancies

Notifications of offices vacant in universities, medical schools, and of vacant resident and other appointments at hospitals will be found at pages 38, 39, 40, 41, and 44 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 42 and 43.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 34

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

584 Encephalitis and Meningitis following Acute Infectious Diseases

Schiödt (*Ugeskrift for Laeger* October 8th, 1931, 995) reports from the Blegdams Hospital in Copenhagen 2 cases of encephalitis or meningitis, as a sequel to infectious diseases or vaccination. Measles terminated fatally in one case owing to encephalitis, and in another owing to meningitis. One case of rubeola was followed by meningitis, ending in recovery, and one case of chicken pox by fatal encephalitis. Parotitis was followed in two cases by meningitis ending in recovery, and by one fatal case of encephalitis. Three fatal cases of encephalitis and one case of meningitis ending in recovery occurred after vaccination. The author comes to the conclusion from a study of the literature and of his own cases that the clinical and pathological picture was so uniform that the use of the term "nosological unit" is justifiable. This observation, and the striking uniformity of the epidemiological behaviour of these cases, suggest that they were all due to a hitherto unknown virus activated by infectious diseases or vaccination. It is not, however probable that the virus is introduced into the body with the vaccine, while these forms of meningitis and encephalitis are presumably caused by one and the same virus it is distinguished in several respects from epidemic encephalitis, both the nature and the localization of the lesions in the two diseases being different. In encephalitis following infections the muscles of the eyes are hardly ever involved, whereas they frequently suffer in cases of epidemic encephalitis.

585 Evolution and Treatment of Pulmonary Tuberculosis

Morin (*Arch Med Chir de l'Appar Respirat*, No 3, 1931, p 229) agrees with Ranke that the development of tuberculosis in the infant passes through three stages, the first being the primary local lesion, with a systemic disturbance indicated by a general sensitiveness and a positive Pirquet reaction. There follows a spread to the serous membranes and the appearance of infiltration in the parenchyma of the lung as the result of direct extension from the tracheo bronchial glands. In this second stage there is a general hypersensitiveness and a markedly positive Pirquet reaction. The third stage is characterized by localization of the lesion, with relative immunity, this corresponds with the adult form of tuberculosis. In children the second stage is the characteristic one, and such forms of local treatment as pulmonary collapse are quite unsuitable. The author believes that tuberculosis in the adult is most often due to the lighting up of an old infection, and not the result of direct fresh infection by the tubercle bacillus. Comparing the merits of phrenicectomy and pneumothorax he states that during the last five years the figures at Leysin were as follows. In 321 cases of artificial pneumothorax 54 per cent improved, 27 per cent remained stationary, and in 19 per cent the disease was aggravated by the operation. Of these cases 55 per cent were bacteriologically negative and 45 per cent positive. Phrenicectomy was employed in 114 cases, of these 58 per cent were improved, 32 per cent remained stationary, and in 10 per cent the condition became worse. Of these cases 30 per cent were bacteriologically negative, and 70 per cent positive. The bacteriological figures were higher in the second group, but the author points out that phrenicectomy was only performed when a pneumothorax could be undertaken, or had failed to produce a negative bacteriological finding. He concludes that just as good results can be obtained with phrenicectomy as with collapse, that the first of these procedures may induce a negative bacteriological finding even when the second has failed, and that complications after phrenicectomy are less than in the case of collapse, the method being more in accordance with physiological principles. In cases where these two methods have failed, or have not been applicable, partial thoracoplasty has produced remarkable results. Morin does not advocate extensive resection of the ribs, he has found that when apical cavities are present on one side or the other only, resection of the first four ribs results in complete cure, and conserves the maximum of healthy lung tissue.

586 The Incubation Period of Measles

P Lereboullet and P Blize (*Arch de Mal des Enf*, August, 1931, p 475) maintain that the incubation period of measles is not always so latent as is stated in the textbooks. Of the numerous symptoms described as occurring in this period some are rare, while others, such as the rise of temperature and increase of the polymorphonuclear leucocytes, are of more value, it is doubtful, however, if they can be of any help in the early diagnosis of measles (as asserted by Combe, Meunier Sebileau, Lucas, Mensi, and others), since they are either too inconstant or ill marked. On the other hand, though the symptoms of the incubation period have only a slight prophylactic value, their pathological interest is undisputable, they indicate that there is a systemic invasion by the measles organism from the very first.

587 Transient Diphtheritic Paralysis

J M Rogaly (*Journ Med Assoc of South Africa*, September 26th 1931, p 691) reports the case of a European boy aged 10 who as a sequel to unrecognized diphtheria developed in course of time palatal paralysis, cardiac arrhythmia suggestive of partial heart block, and flaccid paralysis of both legs. Moreover five weeks after his attack he complained of indistinctness of vision, his pupils were dilated regular reacting to light but not to accommodation and his retinae were marked, complete. Full recovery of vision followed five weeks rest in bed, only a little weakness of his legs then persisting.

Surgery

from the symptoms. In the second case the tumour was only found after an incision had been made through the fascia above the inferior thyroid artery; in the third case the growth was located in the thorax behind the sternum and to the left of the trachea. Both patients showed great improvement after the operation. In the fourth case a small parathyroid tumour was found behind the oesophagus and removed, but a further tumour was located in front of the second and third dorsal vertebrae; it was displaced upwards, the pedicle was ligatured, and the tumour was removed. The patient made a good recovery.

589 Angioma of the Muscles of the Forearm

H. L. ROCHER and UZAC (*Bordeaux Chirurgical*, October, 1931, p. 388) describe angiomata of the voluntary muscles as being of two types: circumscribed or diffuse; as regards their structure they are divided into the capillary and cavernous forms. These tumours may be present for many years, and in exceptional cases they may undergo sarcomatous degeneration. Diagnosis in these cases is extremely difficult, and is rarely made before operation. The symptoms are similar to those found in cases of lipoma or cold abscess, and when near a joint they have been diagnosed as cysts of the joint. When the angioma is circumscribed, its removal is simple, but, in cases where it is diffuse, extensive resection of the whole muscle is sometimes necessary to remove the tumour completely. A case is reported in which a woman, aged 46, had had a tumour of the forearm since childhood. This had gradually increased until it was in shape and size like a half lemon. There was no pain, pulsation, or murmur, but the tumour was rapidly increasing in size. On contraction of the muscles the swelling was found to be fixed and a diagnosis of tumour of the muscle was made. Operation was undertaken under local anaesthesia, and disclosed a large dark-coloured tumour which was closely incorporated with the muscle fibres. The muscle was completely dissected out and removed with the tumour, and the wound closed, drainage being left. The patient made a good recovery, and the after-results were very satisfactory. Microscopical examination showed that the tumour was a diffuse capillary angioma, containing numerous bony nodules which had developed in the connective tissue. In cases where the angioma is large, general anaesthesia in conjunction with a tourniquet is recommended, but for small circumscribed angiomata, local anaesthesia has been found to be satisfactory.

590 Pneumococcal Peritonitis

L. AUROUSSEAU (*Rev. Med. Française*, October 31st, 1931, p. 641) considers pneumococcal infection of the peritoneum is sufficiently frequent to be ranked among other causes of acute peritonitis. He has had 13 cases, bacteriologically controlled, in the last two years, although it is undoubtedly more common in girls than in boys, it is an exaggeration to say it is a disease of girls only. It is often secondary to some pneumococcal focus elsewhere, and infection may pass from the diaphragm, the genital tract, the digestive system, or the blood. Two types have been described the diffuse and the encysted, but the latter is really a further stage of the first. Nearly all cases begin diffusely with an acute onset, general symptoms of grave toxaemia predominating over the local signs. The great difficulty in these cases is the differential diagnosis from other forms of peritonitis. The author suggests that the following symptoms may be helpful in deciding in favour of pneumococcal infection: sudden onset with prodromal sore throat, bronchitis, or other respiratory affection, high temperature, signs of general infection, diffuse abdominal pain without definite localization, disproportion between the general and the local signs, diarrhoea, and the presence of pneumococci in the blood. Treatment turns on the accuracy of the diagnosis; if one can be sure that the peritonitis is pneumococcal, surgical intervention should be postponed, since the mortality in early operation is very high. If there is a probability, but no certainty, that the condition is pneumococcal, it is advisable to wait for a few hours, paying especial attention to the presence of diarrhoea. When no conclusion can be drawn, an operation is essential since the condition may be appendicular peritonitis. In the later stages, when encystment has occurred, there is no question about the desirability of immediate operation.

Therapeutics

591 Liver Extract in Pernicious Anaemia

J. E. CONNERY (*Journ. Amer. Med. Assoc.*, August 29th, 1931, p. 605) comments on the advantages of massive doses of liver extract in cases of pernicious anaemia, especially for those patients who are severely ill and take liver with difficulty and where the necessary dose must be administered by tube. He refers also to the possibility that in certain cases the total amount of extract required to raise the red cell count to a given level may be less when a single massive dose is given than when daily doses are employed, and reports on the treatment of six cases by massive single doses ranging from 30 to 50 phials (Lederle). Reticulocyte rises began on the 2nd to the 4th day; the peak was reached on the 4th day in one case, on the 6th day in four cases, and in one case on the 7th day. The magnitude of the rise was satisfactory in all except one instance where a dose of 50 phials was followed by a peak of only 12 per cent. From the initial level of the red cells the maximum increase of the erythrocytes could not be predicted. The administration of single massive doses of liver extract was without significant effect on the systolic or diastolic blood pressure, or on the blood sugar content. All the patients thus treated were given adequate daily doses of liver extract when the peak of the curve of the red cell count following the single dose had been reached.

592 Ephedrine in Bronchial Asthma

K. TIEFENSEE (*Munch. med. Woch.*, October 23rd, 1931, p. 1824) finds that adrenaline and its allied products (ephedrine, ephetonine, and sympatol) are, next to atropine, the best therapeutic agents in bronchial asthma. The superiority of ephedrine and sympatol over adrenaline lies in their more lasting action, the facility of administration by the mouth, and their slighter toxicity. The action of ephedrine is weaker than that of adrenaline, and it is therefore not advisable in severe cases of bronchial asthma, but it may be useful at the onset or in the prevention of an attack. Administered by the mouth the therapeutic result commences after 20 to 30 minutes given intramuscularly or subcutaneously, after 10 to 15 minutes. The action of the drug is followed by symptoms of languor, sleeplessness, tremors, restlessness, alimentary symptoms, and symptoms referred to the heart and blood vessels suggesting hyperthyroidism. Sympatol is given intravenously, intramuscularly, and subcutaneously in acute cases, or by the mouth at the onset of an attack and in milder cases, but its action is inferior to that of ephedrine or ephetonine. The intravenous injection of sympatol acts similarly to adrenaline. The author discusses the reasons why adrenaline and its allied products generally act more regularly and more strongly than atropine.

593 Protein Therapy of Thrombo-angiitis Obliterans

N. W. BARKER (*Journ. Amer. Med. Assoc.*, September 19th, 1931, p. 841) asserts that the medical treatment of thrombo-angiitis obliterans aims at the relief of pain, rapid healing of open lesions; if these are attained amputation may be avoided. Foreign protein therapy is rational for this disease, since it tends to relieve pain by producing vaso-dilatation, with consequent increase blood supply to the extremities, it accelerates the healing of lesions. Approximately 300 patients have been treated at the Mayo Clinic; the results in 150, in all of whom at least three injections were given, are tabulated. The best preparations were found to be a T.A.B. and typhoid H antigen (a fraction of the

bacteria, emulsified in sodium chloride solution and subsequently killed with 0.5 per cent. phenol). The initial dose is from 15 to 30 million organisms. The number of injections depends on the response, the dose being usually increased by 25 millions at a time, as may be found necessary to keep up the reaction. If prolonged treatment is needed, it is advisable to give a month's rest period after twelve injections. This treatment is but slightly effective in cases with claudication only, and in those with extensive gangrene; the best results are obtained in cases where there is rest pain (pain not induced by exercise), with or without ulcers or limited gangrene.

Dermatology

594 Etiology and Treatment of Eczema

S. W. BECKER (*Journ. Amer. Med. Assoc.*, October 3rd, 1931, p. 983) maintains that there are no clinical or microscopical differences between eczema (with its factor of hypersensitiveness to certain irritative agents) and dermatitis, but that this fact has caused much contention owing to the employment of such terms as allergy, idiosyncrasy, and anaphylaxis. In his opinion, most cases are due to external irritants, usually chemical, but sometimes physical—for example, the rays of the sun. The first step in treatment is, therefore, the identification of the cause, and its removal. In the case of eczema of the hand in housewives, for instance, protection can often be obtained by the use of thin cotton gloves, over which rubber gloves are worn. The cotton gloves absorb the perspiration, and prevent maceration; they should be washed each time before being put on. They should be worn not only when the hands are put in water, but also when the patient is working in dust and dirt. Becker considers that desensitization therapy has been disappointing, although Bloch has shown that eczematous patients are seven times more sensitive to the common irritants than are healthy persons. In the vesicular stage the wet dressing is preferable, 1 grain of potassium permanganate in a pint of water, prepared twice daily, being the best application. It does not become excessively irritating, if inadvertently allowed to dry, and guards against any secondary infection. The dressing should not be surrounded by an impervious substance, such as oiled silk or paper, since free evaporation is desirable. It should be kept wet, but not dripping. After the more acute signs and symptoms have subsided, a sulphonated bitumen zinc paste may be applied; it is renewed each morning and night after gentle removal from the skin with olive oil. Water and soap must be avoided. The paste should be continued even after the skin appears normal, since many recurrences have been caused by too early cessation of treatment. The skin remains hypersensitive for some time after apparent recovery. Becker adds that the term "eczema" is applicable to a definite class of inflammatory dermatoses, and may well be retained in dermatological nomenclature.

595 Dermatitis Venenata due to Shoe Leather

G. M. LEWIS (*Arch. Derm. and Syph.*, October, 1931, p. 597) reports two cases of dermatitis venenata due to shoe leather. Cases arising from this cause are extremely rare; since the condition is not mentioned in textbooks, these two cases call attention to the fallacy of regarding all dermatoses of the feet as fungous in origin. In the first a follicular dermatitis, distributed in bands, and accompanied by severe itching, commenced with the wearing of a particular pair of tan shoes, which were not lined with canvas over the parts affected; recovery promptly occurred as soon as they were discarded. A sample of leather taken from the inner band of the shoes, known in the trade as "bleached kip," applied for twenty-four hours to the inner side of the forearm produced a similar result. The patient's skin was apparently hypersensitive to such leather; since application to the skin of three other subjects produced no such result. In the second case a similar condition occurred after wearing a pair of black shoes in which there was no canvas lining. Samples of leather from the inside of these shoes applied to the forearm produced a pruritic eczematous eruption under each patch. Recovery ensued in both cases when the suspected shoes were discarded. Itching was a marked feature, and in the first patient it began two and a half months before the eruption appeared. Since several methods are employed in tanning it is almost impossible to trace the process used for any given pair of shoes; the patient can only learn by experience his own hypersensitiveness. The possibility of such a cause of dermatosis of the feet should be borne in mind.

596 Treatment of Psoriasis

A. TOMA (*Ann. de Derm. et de Syph.*, October, 1931, p. 1110) has made use of formolized emulsions of the squames of psoriasis, in preparing an autogenous vaccine. The scales, scraped off the lesions with a bistoury or a slip of glass, are triturated in a mortar, and the resultant powder is emulsified in normal serum, in test tubes; formol in 0.25 per cent. dilution is added, and the emulsion is kept at 37°, being frequently shaken. Tests for bacteriological sterility are made after 48 hours, but the emulsion is kept in the incubator for a week before use, to ensure the volatilization of the formol. The concentration of solid in the vaccine is such as to provide a sediment 1 to 2 c.cm. in volume, after 24 hours' standing in an ordinary test tube. The dosage begins with 2 to 3 c.cm. on alternate days, and is increased up to 10 c.cm. doses at intervals of 3 to 4 days; no general reaction of importance has been noted, though the larger doses have sometimes been followed by localized nodular infiltrations which persist for a long time, but eventually disappear spontaneously. Three patients have been treated with good results; one case in a boy of 17, of a year's duration, showing clinical cure after two months' treatment, involving the use of 80 c.cm. of vaccine. The other two cases, both of many years' duration, improved very considerably. In one of these other cases, that of a woman aged 38, the eruptions were subject to seasonal exacerbations in autumn and spring; after this vaccine treatment was begun at the beginning of the autumn of 1930 there was no further exacerbation, and the lesions cleared up steadily. Toma admits that time must show whether these cures may be regarded as permanent, and whether the vaccine is able to check recurrences.

Obstetrics and Gynaecology

597 Diagnosis and Treatment of Puerperal Sepsis

E. R. WHITE (*Med. Journ. of Australia*, September 19th, 1931, p. 352) states that in Australia the death rate from puerperal sepsis is increasing, particularly in Melbourne. Since this condition is an infected wound disease, of which the bacteriology and pathology are similar to those of surgical infections occurring elsewhere in the body, local and general considerations are involved. Sepsis depends on tissue damage and haemorrhage, and prophylaxis is most important. Vaginal examination can almost entirely be replaced by abdominal examination. Efforts should be concentrated on asepsis and a physiological conduct of labour. By preventing exhaustion and loss of blood much can be accomplished in obviating infection; face masks should be worn by all attendants at confinements. Cyllin and brilliant green are advocated as antiseptics. Early diagnosis of sepsis is stressed; suitable nursing must be provided early, but the avoidance of interference is recommended as the safest method of dealing with the uterus in puerperal sapraemia and sepsis; foods rich in vitamins A and D should be given. As a prophylactic measure in all suspected cases, and as a therapeutic measure in early pyrexia, anti-streptococcal serum should be used. In cases where such conservative measures do not prove satisfactory, intrauterine glycerin therapy may be usefully instituted. Vaccines appear to be beneficial only in protracted chronic cases. In acute cases blood

transfusion is of value. Since arsenical compounds seem to have some specific effect upon haemolytic streptococci, their use is indicated in acute sepsis. Surgical treatment is not advocated, apart from suitable drainage of any abscess formation in pelvic cellulitis or peritonitis. Every effort should be made to raise local tissue resistance, and to increase the bactericidal power of the blood.

598 Disappearance of the Placental Site in the Puerperium

J. W. WILLIAMS (*Journ. Amer. Med. Assoc.*, August 22nd, 1931, p. 523) records investigations which indicate that the mucosa of the uterine cervix is restored by the end of the first week after delivery, that the extra-placental endometrium is regenerated during the third week of the puerperium, and that the placental site persists for six or seven weeks, its ultimate disappearance being effected by a process of exfoliation which in great part results from undermining by endometrial tissue. These conclusions are based upon examinations of the uterus removed by operation, or obtainable from necropsies. The disappearance of the placental site does not seem to be the result of an inflammatory process or of extensive necrosis; all the specimens showed an unusual proliferation of the endometrial tissue, which not only covered the placental site, but invaded it in all directions, extending particularly between it and the underlying muscularis layer, and leading eventually to extrusion or exfoliation. Williams adds, however, that further evidence is necessary before this hypothesis of exfoliation can be accepted, and he gives illustrations of histological preparations which appear to clinch his argument. Absorption *in situ* was not observed in his cases.

599 Gingivitis of Pregnancy

S. MONASH (*Arch. Derm. and Syph.*, October, 1931, p. 580) records five illustrative cases in women, aged from 18 to 38, in whom growths were observed on the gums during pregnancy. They began to form at a variable time during pregnancy, usually during the earlier months; they increased in size unless treated, and spontaneously diminished or disappeared after delivery of the child. Since the growth is inflammatory in origin, and is not a true tumour, Monash proposes the term "proliferative gingivitis" of pregnancy. The rapid evolution of the inflammatory process during gestation appears to be due to an exaggerated inflammatory response in some women at that time to irritants that normally provoke only a moderate reaction. Prophylaxis and treatment consist in thorough cleaning and scaling of the teeth, the removal of all greatly decayed teeth and poorly fitting dentures, the correction of the abnormalities of the gums, and instruction in the proper use of the tooth-brush.

600 Abortifacient Apiol Poisoning

TRILLAT, MICHON, and THIERS (*Bull. Soc. d'Obstét. et de Gynécol de Paris*, October, 1931, p. 615) state that apiol, formerly regarded as non-toxic, is very commonly used in France as an abortifacient. They record the case of a woman who admitted having swallowed in three days thirty capsules, each containing 20 cg. of the active product. Abortion ensued, and a week later she was admitted to hospital in a state of collapse, with a temperature of 104°. The general condition improved, but an almost complete anuria followed with great increase of the blood urea (3·29 grams). Bilateral decapsulation of the kidneys was followed by re-establishment of diuresis, complete in a fortnight. This urine, however, contained only 1 per cent. of urea, and at the time of death, thirty days after the operation, the blood urea had risen to 8 grams. Other symptoms were diarrhoea, bleeding from the gums, buccal gangrene, and coma. At the necropsy the uterus, peritoneum, liver, spleen, and lungs appeared normal. Haematuria has previously been described as following apiol ingestion, but the present authors have been able to trace only one other fatal case; in this the death occurred on the thirteenth day from diarrhoea, uterus, epistaxis, bleeding from the gums, and uraemic coma with anuria.

Pathology

601 The Influence of Fatigue on Antibody Formation and Infection

E. FRIEDBERGER, O. ANDERSEN, C. CALLERIO, and I. RUTCHKO (*Zeit. f. Immunitätsf.*, October 16th, 1931, p. 225) report a number of experiments on the effect of acute and chronic fatigue on the antibody content of the blood of laboratory animals, and on their resistance to experimental infection. In the first series guinea-pigs were used, and the normal titre of complement and of natural haemolytic immune body to sheep red cells was determined. Altogether 53 animals were tested, some being acutely fatigued by being made to run round the interior of a revolving drum for short periods, others being made to run at frequent intervals with rest pauses in between. In no case was any difference in the titre of the antibodies found between the normal and the control animals. In the second series rabbits were chosen. The animals were actively immunized by injections of sheep red cells of killed El Tor vibrios. After some days, during which the rabbits were daily fatigued, the antibody titre was determined; again no difference was found between the fatigued and the control animals. After determining the titre, some rabbits were again fatigued, but this did not lead to any greater fall in titre than occurred in the control animals. Moreover, fatiguing the animals before immunization had no apparent effect on the subsequent antibody response. In the third series rats and guinea-pigs were injected intraperitoneally with living El Tor vibrios in such a dose as to cause about a 50 per cent. mortality. Some animals were fatigued after the injection, others both before and after. No difference, however, was noticed, since approximately the same proportion of the fatigued animals died as the controls. The authors conclude that the antibody content of the blood, the formation of antibodies, and resistance to infection, are independent of bodily fatigue.

602 Nuclear Changes in Leucocytes in Vitro

M. CAPPO (*Lo Sperimentale*, October 3rd, 1931, p. 365) has studied the action of filtrates of old typhoid broth cultures on human leucocytes *in vitro*, and has extended the observations of Messini on 70 confirmed cases of typhoid that there is a shift to the left of the Arneth nuclear formula, probably due to a paralysing action of the toxin on the amoeboid movement of the leucocytes. He has endeavoured, also, to gain information about the value and significance of the varying segmentation of the leucocyte nuclei; recent researches have shown that this is not exclusively a function of the age of the mature granulocyte. After preliminary tests indicating that the unfavourable conditions inherent in *in vitro* life of leucocytes caused no alteration in the nuclei or shift of the nuclear index within 6 to 8 hours, a series of observations of stained films and of hanging drops on warm stage was made, in which to the saline solution used for diluting and preserving the blood was added filtrate of old broth cultures of *B. typhosus*; controls of sterile broth cultures were employed. From concentrations of broth filtrate as low as 0.2 to 0.6 per cent., samples were taken at intervals of 30 minutes to 4 hours. The results show a marked lowering of the nuclear index, and a prevalence of two lobed nuclei and diminution of those with four or more lobes, the total number of the leucocytes remaining constant. It was thus possible to demonstrate a marked shift to the left of the nuclear index in leucocytes *in vitro* by the action of filtrates of broth cultures of *B. typhosus*. This is in accord with the shift to the left observed by Messini and others in the course of different toxic infections, and also by the action of certain drugs. Cappo concludes that the morphology of nuclei can vary in the absence of hæmopoietic tissue, and that the presence of little segmented nuclei does not necessarily indicate the passage of young cells into the circulation.

The **SPECIFIC OVARIAN HORMONE**
which normally controls and activates the menstrual cycle

SISTOMENSIN
standardised physiologically

dysmenorrhœa, menorrhagia, hæmorrhages of puberty and menopause, hypoplasia of the uterus, disturbances subsequent to menopause or oöphorectomy.

Tablets Ampoules

PROKLIMAN
(Sistomensin Compound)

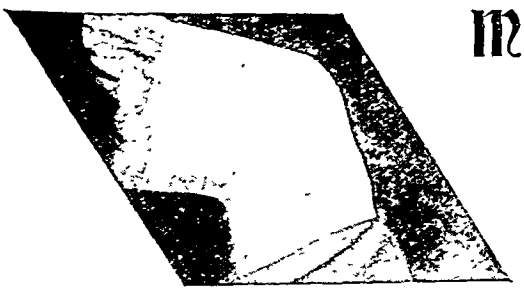
Association of ovarian hormone with therapeutic agents for the prompt relief of the most pronounced troubles of menopause: cardiovascular and nervous troubles, hot flushes, headache, etc.

Tablets

Hydrosoluble Ovarian Substance

AGOMENSIN

causes hyperæmia of the female genital organs. Stimulates the function of the genital glands and menstruation.



Functional amenorrhœa, oligomenorrhœa, sterility, vomiting during pregnancy, etc.

Tablets Ampoules

Elastoplast
BRITISH MADE.
THE ORIGINAL & FINEST ELASTIC PLASTER.

MODERN TECHNIQUE

ELASTOPLAST BANDAGES
In the case of any injury which involves muscles, joints, or ligaments, bandaging with Elastoplast affords, par excellence, the last word in effective treatment.

ELASTOPLAST DRESSINGS
provide speedy and efficient dressings for wounds, incisions, boils, etc.

SEMIPLAST
a new idea in elastic plaster. Only the first turn of the plaster comes in contact with the skin.

CELLONA
The new improved P.O.P. bandage moistens in 5 seconds—sets in 5 minutes. 50% lighter—cleaner—easier to apply and handle than the usual P.O.P. bandage.

VISCOPASTE BANDAGES
(Unna Paste Type)

Literature and cuttings will be sent on request to the manufacturers:

T. J. SMITH & NEPHEW Ltd.,
Dept. B, 42, Tavistock Square, London, W.C.1.

ELASTIC ADHESIVE PLASTER

Also useful for surgical and orthopaedic work generally, and for sprains, strains, dislocations, etc.

Manufactured by EDWARD TAYLOR LTD., Salford, Lancashire. *Branches:* GLASGOW & LONDON.

FOR DEAFNESS

Doctors prefer "ARDENTE" because—

"ARDENTE" STETHOSCOPE.

Mr. R. H. Dent makes a Stethoscope specially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, as evidenced by the interest shown at the last B.M.A. Meeting

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises, giving inconspicuous hearing.
4. It conveys sound from varying ranges and angles.
5. It is entirely different, uncopyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf through various causes.
7. It is helpful for conversation, music, talkies, wireless, home, office, public work, and sports.
8. A wide range—electrical and non-electrical.

FREE HOME TESTS arranged for Doctors and Patients.

Medical Prescriptions made up to the minutest detail.

MEDICAL REPORTS

Commended by all leading medical journals.—Mr. R. H. Dent will be happy to send full particulars and reprints on request, and also arrange demonstrations.

WHERE APERIENTS FAIL SURGICAL BELTS SUCCEED!

The introduction of X-ray photography has swept away many previously held conceptions of the pathology of the abdomen. This new method of examination has shown unmistakably that therapeutic measures such as the use of aperients and intestinal antiseptics are futile in the presence of mechanical displacements. It has revealed that the safe, scientific and effective measure in innumerable cases is to correct the mechanical fault in the engineering system of the abdomen by suitable upward support. Such support is given in specific complaints by Domen Surgical Belts.

Domen Surgical Belts provide ample support upwards from the pelvis. They counteract the downward pull of gravitation—the underlying cause of mankind's tendency to sag. And Domen Belts achieve this upward support without cramping or binding the patient. Domen Belts are light, and durable, and strong. On receipt of your card or a telephone request, full particulars will be forwarded.

ST. ANDREW'S HOSPITAL

FOR MENTAL DISORDERS,

NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or who wish to prevent recurrent attacks of mental trouble, temporary patients, and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms, with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

COURT HALL, KENTON, EXETER,

SOUTH DEVON.

For the care and treatment of Ladies suffering from Mental Diseases. Limited to eight patients. Telephone: Starcross 19.

CLIFFDEN, TEIGNMOUTH, in connection with Court Hall, for early and convalescent cases Cliffden is a large well-appointed house, with lovely views of the South Devon Coast. It is beautifully situated in grounds of 19 acres. The gardens are very attractive, and there is a private road to the beach.

Resident Physicians: BERTHA M. MULES, M.D., B.S.; ANNIE S. MULES, M.R.C.S., L.R.C.P.
Telephone: Teignmouth 289.

TYKEFORD ABBEY, NEWPORT PAGNELL,

BUCKS.

FUNCTIONAL NERVOUS DISORDERS, MEDICAL & CONVALESCENT CASES.

An Approved Nursing Home for reception of Female Cases under the Mental Treatment Act.

The Home is a Mansion of Historical interest, standing in 9 acres of garden and grounds, and is situated 14 miles from Northampton, and 12 miles from Bedford on the main London to Northampton Road, fifty miles from London. Both sexes are accommodated. Psycho-Therapeutic Treatment is used extensively in suitable cases. Radiant Heat, X-Ray, and Ultra-violet Light. Diathermy and Foam Baths. Billiards, tennis, etc. Fees from five gns. per week.

Apply, Dr. D. E. M. DOUGLAS-MORRIS. *Telephone*: Newport, Pagnell 121.

HAYDOCK LODGE,

NEWTON-LE-WILLOWS, LANCASHIRE.

'Phone: 11 Ashton-in-Makerfield.

For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES either voluntarily or under Certificate. Patients are classified in separate buildings according to their mental condition.

Situated in park and grounds of 400 acres. Self-supported by its own farm and gardens, in which patients are encouraged to occupy themselves. Every facility for indoor and outdoor recreation. For terms, prospectus, etc., apply MEDICAL SUPERINTENDENT.

THE COPPICE, NOTTINGHAM.

HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary and Temporary Patients received.

Tel.: 64117. *For terms, etc., apply to the Medical Superintendent.*

The MAUDSLEY HOSPITAL

DENMARK HILL, S.E.5.

Telephone: RODNEY 4841–2.

Telephone: 157 Basingstoke.

RUTHIN CASTLE, NORTH WALES

REDUCTION OF FEES

In view of the present economic position, the inclusive fees at Ruthin Castle, formerly from 17 guineas a week, have been reduced to from 15 guineas a week.

The fees include medical attendance, all scientific investigations that may be needed, such as analyses, bacteriological cultures, the ordinary x-ray examinations, and electrocardiograph readings, all treatment that may be prescribed, such as special diets, insulin, artificial sunlight, electrical treatment, baths, massage, nursing; medicines or vaccines, board and lodging.

The only extra charge is that for a complete alimentary x-ray examination, or for x-ray therapy.

Many people who would go abroad for health will not do so this winter. All the usual forms of treatment are given at Ruthin Castle. The climate is mild. The annual rainfall is 30.5 inches, that is, less than the average for England. There is central heating throughout. Should the accommodation in the Castle not prove sufficient, comfortable rooms can be obtained near by for those undergoing treatment

Address—THE SECRETARY, Ruthin Castle, North Wales. *Telegrams*: CASTLE, RUTHIN. *Telephone*: RUTHIN 66.

TORQUAY

ENGLAND'S MARINE SPA

STRONGLY RECOMMENDED BY THE MEDICAL PROFESSION
FOR WINTER RESIDENCE OR HOLIDAYS.

Extract from the Health Resorts Section, "Medical Directory" for 1931:—
"WINTER CLIMATE—Very sunny, extremely mild, frost and snow practically unknown."

TORQUAY offers every facility for a Winter Cure. Modern Spa Establishment, where all the best treatments are available as at famous resorts abroad, including "Vita" Sun Glass Lounge for ultra-violet radiation.

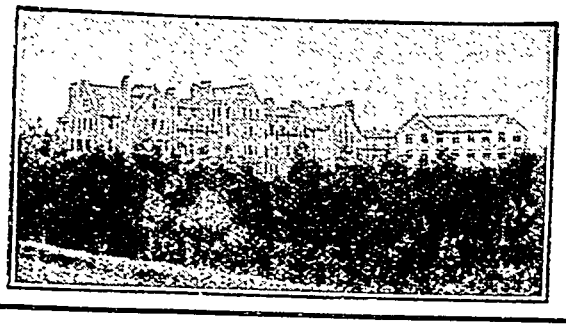
Torquay natural mineral water—of same type as Evian and Vittel.

Travel by the "Torbay Limited," leaving Paddington at 12 noon week-days—the epitome of speed and luxurious comfort. Enquire at Railway Stations and Offices for details of train services, fares, etc., from all parts.

OFFICIAL GUIDE and all information free from PUBLICITY DEPARTMENT, 2, Baths Offices, TORQUAY.

The MUNDESLEY SANATORIUM

The newly opened central building makes the Mundesley Sanatorium the best equipped building in England for the cure of Tuberculosis. All the bedrooms have hot and cold running water, electric light, and wireless head-phones. The new public rooms are spacious and comfortable.



Resident Physicians:
S. VERE PEARSON,
M.D.(Cantab.), M.R.C.P.(Lond.).
ANDREW MORLAND,
M.D., M.R.C.P.(Lond.).
E. C. WYNNE-EDWARDS,
M.B.(Cantab.).

For all information apply:
THE SANATORIUM, MUNDESLEY, NORFOLK.
(Telephone: Mundesley 4.)

The buildings face S.S.W. and are sheltered from the sea by a pine-clad ridge. The sunshine record and dry air complete a perfect site. The medical equipment is of the latest kind, and there is a day and night nursing staff.

Preliminary Examinations

The COLLEGE OF PRECEPTORS holds Preliminary Examinations for Medical Students in London and at Provincial Centres in March, June, September and December. Regulations, apply to the Secretary, College of Preceptors, Bloomsbury Square, London, W.C.1.

EPSOM COLLEGE

Established in 1855 as a Public School with a Royal Medical Foundation.

Patron HIS MOST GRACIOUS MAJESTY THE KING.
President: THE RIGHT HON. THE VISCOUNT BURNHAM, G.C.M.G.
Treasurer: SIR WILLIAM HALE-WHITE, K.B.E., M.D.
Chairman of the Council: RAYMOND CRAWFURD, Esq., M.D., F.R.C.P.
Vice-Chairman of the Council: SIR JOHN F. H. BROADBENT, Bart., M.D.
Head Master of the School: ARNOLD C. POWELL, Esq., M.A.

EPSOM COLLEGE has an exceptionally fine position, with a dry, bracing climate, on the slope of Epsom Downs. The buildings include the War Memorial Chapel, large science buildings, with *lecture theatre and several laboratories for physics*, chemistry, and biology, the Holman art room and the Propert library; a covered swimming bath, heated throughout the year; a gymnasium, a rifle range and drill hall, an armoury, a magnificent new sanatorium (50 beds), with X-ray department, and operating theatre. There are also a museum, a carpenter's workshop, music rooms, tennis and fives courts, a pavilion, and a laundry. Large central heating and hot-water systems have recently been installed. There are over 30 acres of playing fields and 7 acres of vegetables.

The College is "recognised" by the General Council of Medical Education and Registration of the United Kingdom and by the Royal Colleges of Physicians and of Surgeons, and the First Medical Examination of London University may be taken at the College itself.

Boys are also prepared for the Royal Navy, the Army, Air Force, Civil Service, the Universities, and for *Professional or Mercantile Careers*.

There is a large list of valuable Leaving Scholarships. Ten Medical Scholarships, differing in value, and one Dental Scholarship, are awarded annually by London Hospitals, and 33 Leaving Scholarships, ranging in value from £15 to £105 are awarded under varying conditions. Besides these there are one "Dr. Robert Thomson and Phyllis Broughton" Open Entrance Scholarship of £120 a year, one "Domett Stone" *Open Entrance Scholarship of £110 a year*, and four "Salomons" Entrance Scholarships of £50 a year each. "Hugh Vardon" Scholarships of £24 and Junior Open Scholarships of £60 are awarded annually.

ANNUAL FEES.—Sons of Medical Men, £135. Those who are not the sons of Medical Men, £155. Day Scholars, £57. These fees are inclusive, covering all such items as books and stationery, medical attendance for boarders, bed linen, laundry, boxing, fencing, shooting, swimming, physical training, O.T.C., Scouts. In short, a parent when considering the cost of education at various Public Schools has something most definite to go on at Epsom College.

NEW SANATORIUM.

The new Sanatorium completed in September, was opened on the 3rd October, 1931, by Lord Dawson of Penn in the presence of a large and distinguished gathering. It is generally conceded to be the finest Public School Sanatorium in England. Practically all the recommendations of the Ministry of Health contained in their pamphlet on "Public School Sanatoria" have been embodied in its construction.

The building, which is of three stories, has a fine position, nearly half a mile away from any public road, with its long axis east and west, so that all wards face south. *An illustrated booklet on the* Sanatorium will gladly be sent on application.

Important factors in the design are (1) Opening by sections; (2) Facility for dealing, at one and the same time, with ordinary ailments and accidents, and four distinct simultaneous infections common to school boys; (3) Administration in normal times by a small staff; (4) Effective segregation of infectious cases from non-infectious; (5) Prompt X-ray examination in cases of injury; (6) Performance of minor operations under surgically suitable conditions; (7) Indoor recreation for convalescents; (8) Open-air balconies and sun-lit cheerful solaria for patients that require them; (9) Accommodation for unmarried masters when sick.

A number of beds and one of the wards already carry distinctive names, which is in accordance with the resolution that a gift of £10,000 should confer on the donor the right to name the main Sanatorium, one of £5,000 the Isolation Wing, one of £3,000 the right to name a large ward, and one of £1,000 a small ward, *and gifts of £100 a single bed.*

The building has cost £28,000, towards which nearly £9,000 has kindly been given to date, and the Council will welcome further donations towards paying off the balance of the cost.

ROYAL MEDICAL FOUNDATION.

FIFTY FOUNDATION SCHOLARS receive an education of the highest class in Epsom College, and are boarded, clothed, and maintained at the expense of the Foundation. They must be elected, after approval by the Council from among the sons of necessitous Medical Men who have been Registered Medical Practitioners for five years.

FIFTY ORDINARY PENSIONERS, who must be legally qualified Medical Men registered for five years, or the Widows of such, receive an annual pension. They must be not less than 60 years of age at the time of their application for admission as candidates.

ABOLITION OF VOTING and EXTENSION OF BENEFITS TO MEDICAL WOMEN AND THEIR SONS.

In the past the above Pensioners and Foundation Scholars have been elected by the Governors voting *by ballot, but at an Extraordinary General Meeting* held on the 26th June, 1931, the Governors unanimously decided to abolish this system, and to empower a Special Committee (composed of ten members of Council and ten Governors who are not members of the Council) to elect the Pensioners and Foundation Scholars concerned.

They further decided to extend the benefits to Medical Women and the sons of Medical Women, hitherto excluded under the College Acts of Parliament.

To accomplish this a new Act of Parliament is essential, but this is unlikely to receive Royal Assent in time to abolish voting for the year 1932.

A sum of close upon £9,000 is required annually to maintain fifty Foundation Scholars and fifty Pensioners, yet this leaves much destitution in the profession untouched. The Council earnestly plead for more and larger subscriptions, so that they may extend the work to the relief of this distress.

The profession and the public are therefore asked to make the Royal Medical Foundation attached to the College a refuge in time of trouble for all these members of a great profession and their children who fall on evil days.

Donors of 10 guineas, and collectors of 20 guineas, are Life Governors of the College, subscribers of one guinea annually are Governors during the continuance of their subscriptions.

W. L. GIFFARD (Major), Secretary.
Office, 49, Bedford Square, W.C.1.

CITY OF LONDON MATERNITY HOSPITAL,

CITY ROAD, E.C.1.

Chemistry, Physics, and Biology Labs.
MANCHESTER TUTORIAL COLLEGE, 327, Oxford Road, Manchester.

Royal College of Physicians of EDINBURGH.

KIRK DUNCANSON FELLOWSHIP FOR MEDICAL RESEARCH.

In accordance with the Bequest of Mrs. Isabella Kirk Duncanson to commemorate the late Dr. J. J. Kirk Duncanson, the Council of the Royal College of Physicians will make an award of a Kirk Duncanson Fellowship in January, 1932. The Fellowship will be awarded annually for a period of one year. It may be renewed to the same beneficiary for two additional periods of one year each. The emoluments will be upwards of £150 for the first year, about £250 for the second year, and about £350 for the third year. In recognition of Dr. Kirk Duncanson's interest in the Diseases of the Ear, Nose, and Throat, some preference will be given to the claims of candidates who propose to devote themselves to research in that branch of Medicine.

Applications and recommendations, with particulars of the special line of research contemplated and of the place where the investigations are to be conducted, should be in the hands of the Secretary of the College, 9, Queen Street, Edinburgh, by January 15th, 1932.

Breconshire County Council.

APPOINTMENT OF COUNTY MEDICAL OFFICER OF HEALTH.

Applications are invited from duly registered Medical Practitioners (male), holding a Degree or Diploma in Public Health, for the whole-time appointment of Medical Officer of Health for the County, School Medical Officer, and Medical Officer for Mental Deficiency, Maternity and Child Welfare, and Venereal Diseases work, including such other duties as may from time to time be assigned to the officer by the County Council.

Basic salary £800 per year, subject to a temporary deduction of £60 per year during the present financial emergency, with travelling and subsistence allowances according to the County Scale.

Candidates must be prepared to provide and drive a motor car to carry out the duties of the appointment.

Preference will be given to candidates having a knowledge of Welsh, and with previous experience in Refraction and Orthopaedic work.

Applications, stating age and qualifications, accompanied by copies of not more than three recent testimonials, must be sent to reach me not later than January 2nd, 1932.

ALBERT JOLLY,
Clerk of the Breconshire County Council.
County Hall, Brecon.
December 14th, 1931.

Royal East Sussex Hospital, HASTINGS. (Beds 120.)

Applications are invited for the post of HONORARY ANAESTHETIST to the Hospital.
Applicants must be Fellows or Members by Examination of the Royal College of Physicians of London, Edinburgh, or Ireland, or be a Graduate in Medicine of one of the Universities of the United Kingdom or Ireland, and also be duly registered under the Medical Acts.
Information as to duties may be obtained from the Secretary.
Applications, with three copies of recent testimonials, should reach the Secretary not later than January 4th, 1932.

WILFRID G. KEMSLEY,
Secretary.

Rotherham Hospital.

Wanted, CASUALTY HOUSE SURGEON (male), qualified. Salary £150, with board, residence, and laundry. 130 Beds.
Applications, with copies of recent testimonials, to be sent to the Secretary, G. W. ROBERTS, 8, Moorgate Street, Rotherham.

University of the Witwatersrand, JOHANNESBURG.

SENIOR LECTURER IN ANATOMY.

Applications are invited for the above post from medically qualified candidates. The teaching embraces Histology in addition to Gross Anatomy.

The salary at present offered is £516 per annum, rising by annual increments of approximately £26 to £726 per annum, but these rates may be affected by the financial position of the country, and candidates who have applied will be informed of any reduction which may take place.

Participation in the University Teachers' Provident Scheme is compulsory. This scheme provides for a contribution by the members of 6 per cent. of their basic salary (£450—£25—£650), the fund contributing the same amount. A higher commencing rate of salary may be approved in the case of a candidate possessing special qualifications or experience.

An amount of £60 will be allowed for travelling expenses, and half salary paid from the date of embarkation to the date of arrival in Johannesburg.

The appointment, which is a full-time one, is subject to all the conditions and rules now in force, and duty is to be assumed as soon as possible after appointment, which will be communicated by cable.

Further particulars as to the conditions of service may be obtained from the Secretary, Office of the High Commissioner for the Union of South Africa, South Africa House, 73, Strand, London, W.C.2, from whom forms stating the particulars required may be obtained.

Applications, in duplicate, accompanied by testimonials, should reach the High Commissioner's Office not later than Jan. 15th, 1932.

Sudan Government.

WELLCOME TROPICAL RESEARCH LABORATORIES, KHARTOUM.

Applications are invited for the post of BACTERIOLOGIST at an initial rate of pay £E.660 or £E.720 per annum (according to age and qualifications), with five or six biennial increases to £E.1,080, and thence after three years to £E.1,200. These rates of pay as well as the conditions of service are subject to Government rules and regulations from time to time in force. (£E.1 = £1 0s. 6d.)

Applicants must be unmarried, and will be expected to take up their duties immediately.

Applications, stating age, degrees, experience (with special reference to Pathology), and copies of testimonials, should be sent to the Director, Wellcome Tropical Research Laboratories, Khartoum, Sudan.

Further particulars regarding this post may be obtained on application to the Controller, Sudan Government, London Office, Wellington House, Buckingham Gate, London, S.W.1.

Rowley Regis Urban District COUNCIL.

DEPUTY MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER.

Applications for the above appointment are invited from single or widowed women. Applicants must be registered Medical Practitioners and possess the Diploma in Public Health. The salary offered is at the rate of £500 per annum, rising by annual increments of £25 to £700, subject to a temporary deduction of 10 per cent.

A form of application can be obtained on receipt here of a stamped addressed foolscap envelope.

Completed forms, accompanied by copies of not more than three recent testimonials, should be addressed to the Clerk, Rowley Regis Urban District Council, Council Offices, Old Hill, Staffordshire, so as to arrive not later than January 4th, 1932

The Hospital for Sick Children, NEWCASTLE-UPON-TYNE.

The Committee of Management have declared a vacancy for an HONORARY SURGEON.

Applications, stating date of birth and qualifications, are invited for this appointment, and should be sent to the Secretary, Mr. NEIL BRODIE, 18, City Road, Newcastle, accompanied with copies of three recent testimonials, on or before January 9th, 1932.

Canvassing a disqualification.

St. Thomas's Hospital.

VACANCIES.

The appointment of TWO ASSISTANT SURGEONS to the Ear, Nose and Throat Department.
Candidates must be Fellows of the Royal College of Surgeons (England). Applications, with testimonials and full details of academic career, to be sent to the Clerk to the Governors, on or before December 31st, 1931.

London County Council.

Applications are invited for appointment for one year only to the position of ASSISTANT MEDICAL OFFICER, Grade II, at the undermentioned Hospitals.

The persons appointed will be required to carry out such duties as may be assigned by the Medical Superintendent and, should occasion arise, to assist at any of the other establishments under the control of the Council.

Where residential accommodation is available the successful candidate will be required to live in the Hospital.

The salary in each case is £250 a year, together with board, lodging, and washing, or a non-residential allowance of £150 a year in lieu (subject to review). Candidates must be duly qualified Medical Practitioners of at least one year's standing and have held a resident appointment in a General Hospital for at least six months.

Archway Hospital, Archway Road, Highgate, N.19.
Fulham Hospital, St. Dunstan's Road, Hammersmith, W.6.
*Hackney Hospital, High St., Homerton, E.9.
Highgate Hospital, Dartmouth Park Hill, N.19.
*Mile End Hospital, Bancroft Road, Mile End, E.1.
†New End Hospital, Hampstead, N.W.3.
†Norwood Children's Hospital, Norwood, S.E.27.
*Paddington Hospital, Harrow Road, W.9.
*St. George-in-the-East Hospital, Raine Street, Wapping, E.1.
St. Luke's Hospital, Sydney Street, S.W.3.
*St. Mary Abbots Hospital, Marloes Road, Kensington, W.8.
St. Mary Islington, Highgate Hill, N.19.
*St. Nicholas, Plumstead, S.E.18.

* No accommodation for a woman.
† Non-residential appointment.

Only one form of application is required for these vacancies, and successful candidates will be allocated in accordance with the requirements of the service. Consideration will, however, be given to any preference which candidates may express.

Forms of application obtainable (stamped addressed foolscap envelope necessary) from Medical Officer of Health (Staff Division 4a), County Hall, Westminster Bridge, S.E.1, returnable by January 1st, 1932. Canvassing disqualifies. Further inquiries should be addressed to Medical Superintendents at the Hospitals.

Lancashire County Council.

APPOINTMENT OF DENTAL SURGEON.

The Lancashire County Council propose to appoint a full-time Dental Surgeon, and invite applications from fully qualified and registered Dental Surgeons, who must not be over 40 years of age.

The duties of the post are:
1. The dental inspection and treatment of children under the Education Act.
2. The dental inspection and treatment of Expectant and Nursing Mothers and of young children, under the Maternity and Child Welfare Acts.
3. Such other duties as may, from time to time, be imposed by the Education and Public Health Committees.

The salary will be at the rate of £600 per annum (less temporary emergency abatement of £31 per annum), together with the usual allowances for travelling, etc. The person appointed will be required to pass a medical examination and to contribute towards the Council's Superannuation Scheme.

Applications must be made upon a form which can be obtained, together with further particulars, from County Medical Officer of Health, School Medical and Child Welfare Department, County Offices, Preston, to whom the completed form should be returned not later than January 9th, 1932.

All communications must be endorsed "Dental Surgeon." Canvassing is strictly forbidden, and will disqualify.

GEORGE ETHERTON,
Clerk of the County Council.
County Offices, Preston.

Hôpital Français,

172, Shaftesbury Avenue, W.C.2.

JUNIOR RESIDENT MEDICAL OFFICER (male) required for a period of three months from now. Registered, unmarried, speaking French fluently. Salary £100 per annum, with full board and laundry. Candidate should state in their applications, with three copies of recent testimonials, as soon as possible to—

J. KNECHT, Secretary.

St. Paul's Eye Hospital, OLDHALL STREET, LIVERPOOL.

HOUSE SURGEON required immediately for six months appointment. Salary £145, board, residence, etc. Applications, with copies of testimonials, should be sent to the Secretary of the Hospital, on or before January 2nd, 1932.

INDIAN MEDICAL SERVICE

Recruitment of European Officers.

Applications are invited from medical men for permanent commissions in H.M.'s Indian Medical Service. The terms offered include a gratuity of £1,000 on retirement after six years' service, or £2,500 after 12 years' service, together with free return passages for those who no longer desire to remain in the Service. In other respects the terms will be as detailed below.

Candidates must be British subjects under 32 years of age at the time of application, and must be registered under the Medical Acts in force in Great Britain and Northern Ireland.

CAREERS.

The Indian Medical Service offers wide opportunities of medical experience, including clinical, preventive, specialist, and research work. At the beginning of his career an officer is employed on the military side, which has medical charge of the Indian Army. Promotion is on a time scale up to the rank of Lieutenant-Colonel, and by selection to the ranks of Colonel and Major-General. An officer may apply after one year's Indian service to have his name registered for transfer to the civil side, from which appointments are made to Civil Surgeoncies, which are established at the principal civil centres to provide for the medical needs of civil officials and for general medical administrative purposes; to specialist (for example, public health and bacteriological) services; to research posts, and to professorships at the Medical Schools.

NOTE.—It is not possible to state at present what, if any, prospects of employment on the civil side will be open to Indian Medical Service Officers under the proposed new constitution for India.

PAY.

Owing to the state of financial emergency at present prevailing in India the existing monthly rates of pay, which are as follows, are being subjected, under the authority of the Secretary of State in Council, to a temporary reduction not exceeding 10 per cent.

Rank.	Service in Rank.	Basic Pay	Overseas Pay	Years of Total Service
1	2	3	4	5
		Rs	Rs	
Lieut.	—	500	140	1st
			140	2nd
			140	3rd
Capt.	(i) During first 3 years' service as Captain	670	140	4th
			£15	5th
			£15	6th
	(ii) With more than 3 and less than 6 yrs' service as Captain	750	£25	7th
			£25	8th
			£25	9th
	(iii) With more than 6 years service as Captain	870	£25	10th
			£25	11th
			£25	12th
Major	(i) During first 3 years service as Major	900		
	(ii) With more than 3 and less than 6 years' service as Major	1100		
	(iii) With more than 6 years service as Major	1250		
Lieut.-Col.	(i) Until completion of 23 years total service	1500	£30	13th and over
	(ii) During 24th and 25th years service	1600		
	(iii) After completion of 25 years total service	1700		
	(iv) When selected for increased pay	1850		

EXTRAS.—In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the Indian Medical Service. Special high rates of pay are also attached to the numerous administrative appointments open to officers in both branches of the Service.

ANTEDATES IN COMMISSION.

Any service rendered by an officer during the war as a medical or combatant officer, or in a position usually filled by an officer, may be counted as service for increments of pay, promotion retirement and retired pay, but not for gratuity.

One half of any service in the ranks during the war may be counted as service for retirement and retired pay only.

Candidates possessing certain higher medical qualifications may be granted an antedate of one year in their commissions. Past service in certain hospital appointments may also render candidates eligible for an antedate of one year. Persons holding or about to hold resident posts at recognized hospitals may be seconded in those posts for a period not exceeding one year. The maximum period of antedate, secondment, or antedate and secondment combined, admissible under this paragraph, is limited to one year.

OUTFIT ALLOWANCE.

Officers on appointment will receive an allowance of £50 towards the cost of outfit.

PRIVATE PRACTICE.

With the exception of Administrative Officers, military or civil, and officers holding certain special appointments, officers are not debarred from taking private practice, so long as it does not interfere with their proper duties.

LEAVE.

Leave can be taken at reasonable intervals, and adequate rates of leave pay are provided. Extra leave (known as study leave), which may not exceed 12 months in all during an officer's service, may be granted to officers desirous of pursuing special courses of study of a post-graduate nature. During such leave, study allowance, at present fixed at the rate of 12s. a day in the United Kingdom, £1 a day on the Continent of Europe, and £1 10s. a day in the United States of America, is granted to an officer in addition to ordinary rates of leave pay.

PENSIONS.

The rates of pension are as follows	Per annum.
	£
After 17 years' service for pension	400
,, 18 ,, ,, ,, ...	430
,, 19 ,, ,, ,, ...	460
,, 20 ,, ,, ,, ...	500
,, 21 ,, ,, ,, ...	540
,, 22 ,, ,, ,, ...	580
,, 23 ,, ,, ,, ...	620
,, 24 ,, ,, ,, ...	660
,, 25 ,, ,, ,, ...	700
,, 26 ,, ,, ,, ...	750
,, 27 ,, ,, ,, ...	800

These rates are subject to alteration on account of a rise or fall in the cost of living as compared with the year 1919 to an extent not exceeding 20 per cent. in all. With effect from October 1st, 1931, a reduction of 8½ per cent. has been made on this account from the amounts shown.

There are additional pensions ranging from £65 to £250 per annum for officers who have held administrative appointments.

PASSAGES.

An officer on appointment is provided with free passage to India. The wives and families of officers who are married prior to the date of the officers' embarkation on first appointment will also be provided with free passage to India, subject to the payment of messing charges.

Officers and their families are also eligible for passage concessions under which they are granted a certain number of return passages home at Government expense during their service.

INSTRUCTION PRIOR TO EMBARKATION.

Officers are required to undergo courses of instruction at the Royal Army Medical College and at Aldershot, lasting approximately six months, prior to their embarkation for India on first appointment.

Full details regarding these appointments and forms of application may be obtained from the Under-Secretary of State for India, Military Department, India Office, London, S.W.1. The Selection Committee will meet at the India Office early in January next, and the selected candidates will be required to join a course of instruction commencing early in February, 1932, prior to sailing for India in the Autumn of 1932. Applications should be submitted as soon as possible.

County Borough of Halifax.

HEALTH COMMITTEE.

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)
(FOUNDED 1880.)

Tele Address: Triform, Wesdo—London.

12, Stratford Place, Oxford Street, W.1.

Telephone: Mayfair {1782 1783

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION have every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUM TENENS.

Assistants and Locum Tenens can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Accounts, etc.

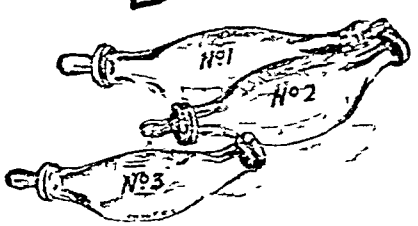
"ITS WEIGHT AT BIRTH WAS ONLY 4 lbs."

July 9th, 1931

Dear Sirs,



The following case will, I am sure, interest you. Baby Lowe was born on November 4th, 1929, at the 28th week Its weight at birth was 4 lbs. It was put in an incubator and fed with a fountain-pen filler. First it was fed from the breast, then on a spray-process dried milk, and finally on a peptonised food.

It was brought to the Motherhood Bureau on June 10th, 1930—aged 7 months. Its weight was 8¾ lbs It was still fed on peptonised feeds and could take only 4 feeds a day, and vomited after these, and was therefore losing weight.

Baby Lowe was put on a Lacidac Half Cream—4 measures to 6 ozs of water—with Mead's Dextri Maltose No. 1, 4-hourly feeds Within a week the sickness had improved, the baby had begun to gain a little weight, and by July 10th its weight was 9 lbs It was then put on Full Cream Lacidac and the appropriate additions of Brestol. In August Cow & Gate Rusks were added to the diet, and mixed feeding was commenced as the teeth were beginning to erupt.

In the 5 months from July 11th, 1930, to January 7th, 1931, the child gained 8 lbs., and at the last report on May 28th, 1931, was very bonny and well and was walking and climbing everywhere

PURGATIVES AND MALNUTRITION

The dangers attending the administration of irritant purgatives to delicate and debilitated patients have long been recognised.

Whilst a certain amount of immediate relief may be thus obtained, the disturbing effect on the autonomic nervous system and the malnutrition resulting from irritation of the absorptive mechanism frequently outweigh the temporary alleviation. There appears, also, to be considerable risk of malnutrition in the constant use of laxatives of the so-called lubricating type. The covering of the mucous membrane of the intestines with a thin coating of oil can hardly fail to lessen the absorption of aliment. Moreover, it was found by Channon and Collinson that a portion of the mineral oil is liable to be absorbed and to accumulate in the liver. The pathologic possibilities of such accumulation need no stressing.

For the relief of moderate degrees of constipation, in cases in which the fullest nutrition is important, no safer or more reliable laxative can be found than an effervescent preparation of the standard of Eno's "Fruit Salt."

In Eno's "Fruit Salt," it is claimed, we have at our disposal a carefully compounded, pure and standardised preparation, entirely free from the harsh and disagreeable sulphates of soda and magnesia. Eno's "Fruit Salt" has been used and prescribed by thousands of doctors for over half a century, during which time its reputation has become world-wide.

ENO'S "FRUIT SALT"

"Urgent Abdominal Diagnostics"

The Proprietors of ENO'S Fruit Salt will deem it a privilege to send to any member of the Medical Profession a copy of the latest of their series of "Medical Reminders"—with or without a bottle of their preparation as desired. "Urgent Abdominal Diagnostics" summarises the salient facts which need to be ever at the front of the mind when faced with an abdominal emergency. The diseased conditions dealt with include those which most often call for immediate surgical attention. It is bound in black morocco limp to conform to the style of the previous publications in this series.
